PREFACE TO SUPPLEMENT A TO

VOLUME II: MOBILE SOURCES

Compilation of Air Pollutant Emission Factors, AP-42, reports data on emissions of atmospheric pollutants for which sufficient information exists to establish realistic emission estimates. The highway source data presented in this supplement are based on MOBILE4, a computer program issued by the EPA in March 1989, which estimates fleet emission rates for hydrocarbons (HC), carbon monoxide (CO), and oxides of nitrogen (NOx) for any calendar year between 1960 and 2020. The emission factors for off-highway mobile sources are presented in Section II of the 4th edition of AP-42 (September 1985), and are not revised in this supplement. EPA will issue additional supplements to this volume, updating the emission factors for particulates, transit buses, and off-highway mobile sources, as new data are available.

Comments and suggestions regarding this document are appreciated and should be addressed to:

Part I - HIGHWAY MOBILE SOURCES

INTRODUCTION

This document officially revises all previous emission factor (AP-42) documents for highway mobile sources. Also, this document will be periodically revised as the emissions and in-use vehicle operational characteristics vary from those presented.

A. PURPOSE

This document was generated to present more recent emission factor information for highway mobile sources. As such, the affected sections of the September 1985 Compilation of Air Pollutant Emission Factors: Highway Mobile Sources document (Introduction, Chapters 1-8, and Appendixes A-K) are outdated. Many of the emission rates contained in this document are found in EPA's mobile source emission model, MOBILE4.

B. MAJOR DIFFERENCES FROM 1985 COMPILATION DOCUMENT

The differences between the emission factors presented in this supplement and the September 1985 Compilation Document are listed below:

1. Calculation Methodologies

- a. Fuel volatility effects on hot soak, diurnal, and exhaust emissions are accounted for.
- b. Running loss emissions (evaporative emissions generated when a vehicle is operating) are added to the model. Emissions are expressed as functions of fuel volatility and ambient temperature.
- c. Refueling emissions are added.

8

- d. A set of trip- and emissions-weighted temperatures, based on the daily minimum and maximum ambient temperatures, are calculated in the model to be used for estimating exhaust, hot soak, and running loss emissions. The daily minimum and maximum ambient temperatures are used to calculate diurnal emissions.
- e. Two sets of emission deterioration rates as a function of accumulated mileage (one applicable to the first 50,000 miles of vehicle operation, and a second applicable to mileage accumulation over 50,000 miles) are used for both HC and CO emissions of 1981 and later model year light-duty gasoline-powered vehicles.
- f. Hot stabilized idle emissions are in units of grams per hour. For late model year gasoline-powered vehicle types, the idle emission rates are updated based on in-use data, as functions of hot FTP exhaust emission rates.
- g. Trip characteristics (trip days, full diurnal, partial diurnal, multiple diurnal, and no diurnal days) are being accounted for in the calculation of evaporative emissions in grams per mile. Trips per day and miles per day parameters are expressed as functions of vehicle age.
- h. Emission reduction credits from a motor vehicle inspection and maintenance program and/or an anti-tampering program are estimated depending on several user-specified parameters, such as waiver rate, compliance rate, type of program, etc.

2. Emission Data and Other Parameters

- a. The hot soak and diurnal emission rates are based on test results using three levels of fuel volatility, with varying ambient temperatures.
- b. More data for basic exhaust emissions are incorporated for all gasoline-powered vehicle types and heavy-duty diesel-powered vehicles, usually for the later model years and across wider mileage ranges.
- c. More representative fleet characterization data (registration and mileage accumulation vs. age distributions) are used for each vehicle type.

- d. New methane offsets are developed for the three light-duty gasoline-powered vehicle types based on more methane HC emissions data.
- e. More temperature correction factor data, especially from fuel-injected technologies, have been incorporated for light-duty gasoline-powered vehicle types. For ambient temperatures higher than 75°F, a combined temperature and fuel volatility correction factor is used to adjust exhaust emissions.
- f. More speed correction factor data, especially from tests over very low speed (\leq 5 mph) cycles, have been incorporated for light-duty gasoline-powered vehicle types.
- g. An additional category, "missing gas cap," is added for tampering rates and tampering offsets. More tampering data have been incorporated for light-duty gasoline-powered vehicle types.

3. Regulations

- a. The emission rates for the 1988 and later model year trucks reflect the emission standards and regulations that have been promulgated at the time of this update (see Appendix A).
- b. Emission reduction credits from a fuel volatility control program can be accounted for (see Section E below). Refueling emission impacts from either Stage II or onboard refueling vapor recovery system control programs can also be modeled (see sections F and G below).

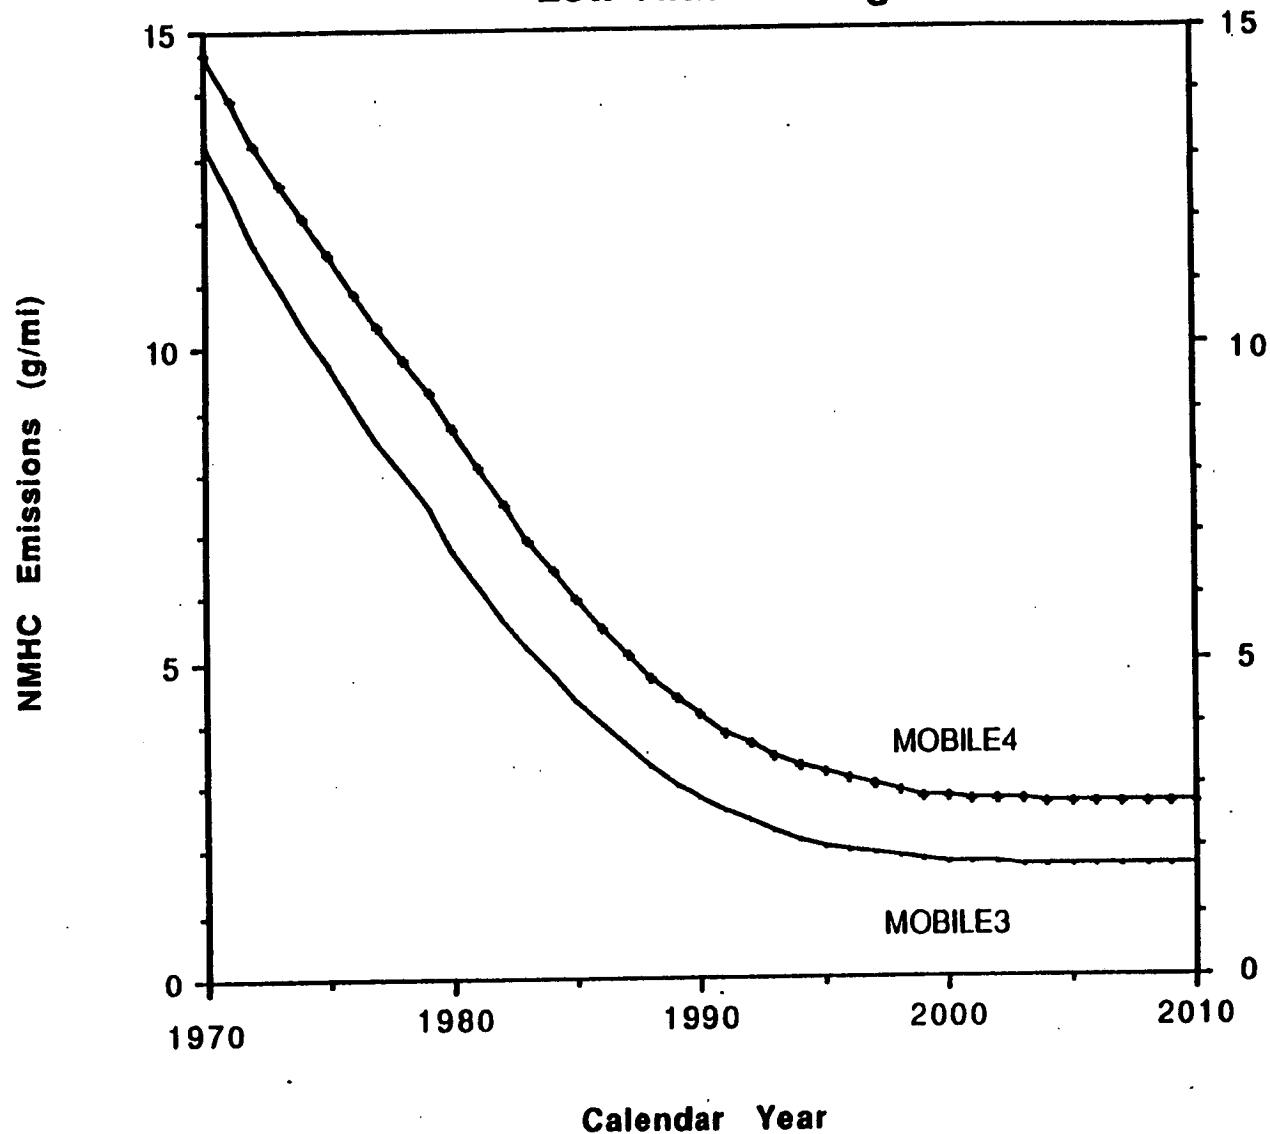

[Note: Regulations and emission standards mandated by the Clean Air Act Amendments of 1990 are not accounted for in the emission factors presented in this supplement.]

In summary, all of the changes mentioned above have an impact on the calculated emission factors. To illustrate the differences, six figures are given. Each figure represents emissions at an average speed of 19.6 mph, temperature of 75°F, and operating mode VMT percentages of 20.6% for cold start, 52.1% for stabilized, and 27.3% for hot start, FTP ambient diurnal temperatures of 60° to 84°F. The six figures are grouped into two sets: low altitude and high altitude

emissions for January 1 of calendar years 1970 through 2000. The figures represent the emission levels for all eight vehicle types combined. Each set of graphs is composed of the three pollutants: nonmethane HC, CO, and NOx. The emissions predicted by the 1985 Compilation methodology were generated by the MOBILE3 computer model, using the default of 9.0 psi RVP certification fuel for exhaust emissions, and 11.5 psi fuel for evaporative emissions. The emissions predicted by the 1989 AP-42 methodology were generated by the MOBILE4 computer model, as corrected on May 19, 1989, using the in-use fuel volatility level of 11.5 psi RVP for all emissions.

C. VEHICLE INSPECTION AND MAINTENANCE PROGRAMS

As in MOBILE3, if a motor vehicle inspection and maintenance (I/M) program is in effect in the area for which emission factors are being calculated, emission reduction credits can be taken.

The emission reduction credits attributable to an I/M program vary according to the type of program in effect. The MOBILE4 credits for an I/M program depend on the following nine factors:

1. The calendar year the I/M program is implemented.
2. The estimated failure rate (stringency factor) among the pre-1981 model year LDGVs or pre-1984 model year LDGTs.
3. The oldest and newest model years involved in the I/M program.
4. Percent waiver rate.
5. Percent compliance rate.
6. Frequency of I/M inspections: annual or biennial.
7. The four vehicle types potentially affected by the I/M program: LDGVs, LDGT1s, LDGT2s, and HDGVs.
8. One of the three test types: idle test, 2500 RPM idle test, or loaded idle test.
9. One of the three I/M program designs: centralized, decentralized and computerized, or decentralized and manual.

The I/M credits are not tabulated in this document but are built-in to the MOBILE4 computer program.

D. VEHICLE ANTI-TAMPERING PROGRAMS

As in MOBILE3, emission reduction credits can also be taken if an anti-tampering program (ATP) is in effect in the area for which emission factors are being calculated.

The emission reduction credits attributable to an ATP vary according to the program type. The MOBILE4 credits for an ATP depend on the following seven factors:

1. The calendar year in which the ATP is implemented.

2. The oldest and newest model years involved in the ATP.
3. The vehicle types affected by the ATP: LDGVs, LDGT1s, LDGT2s and HDGVs.
4. One of the two ATP designs: centralized or decentralized.
5. Frequency of the anti-tampering inspections: annual or biennial.
6. Percent compliance rate.
7. The extent of the inspections (i.e., types of components inspected). The eight components that may be included in an ATP are: air pump, catalyst, fuel inlet restrictor, tailpipe lead detection, EGR, evaporative control system (canister, purge lines, etc.), PCV, and fuel cap.

These ATP credits are not tabulated in this document, but are built-in to the MOBILE4 computer program.

E. FUEL VOLATILITY CONTROL PROGRAM

Emission reduction credits can be taken if a fuel volatility control program is in effect in the area for which emission factors are being calculated.

The emission reduction credits attributable to a fuel volatility control program vary according to the following three parameters:

1. The base (pre-control) fuel volatility level.
2. The controlled fuel volatility level.
3. The calendar year in which the fuel volatility control program is implemented.

F. STAGE II VAPOR RECOVERY SYSTEM CONTROL PROGRAM

Refueling emission reduction credits can be taken if a Stage II vapor recovery system control program is in effect in the area for which emission factors are being calculated.

The refueling emission reduction credits attributable to a Stage II vapor recovery system control program vary according to the following four parameters:

1. The calendar year in which the Stage II vapor recovery system control program is implemented.
2. Length of phase-in period (from one to three years) allowed for all stations to complete installation.
3. Percent efficiency for LDGVs and LDGTs.
4. Percent efficiency for HDGVs.

G. ONBOARD VAPOR RECOVERY SYSTEM CONTROL PROGRAM

Emission reduction credits can be taken if a nationwide onboard vapor recovery system control program is in effect.

The emission reduction credits attributable to a nationwide onboard vapor recovery system control program vary according to the following parameters:

1. The model year in which the onboard vapor recovery system control program is implemented.
2. The four vehicle types covered are: LDGVs, LDGT1s, LDGT2s, and HDGVs.

H. REACTIVE VERSUS NONREACTIVE HYDROCARBON EMISSIONS

Available scientific evidence indicates that methane and a few other nonreactive organic compounds do not contribute significantly to ozone formations. EPA's Volatile Organic Compound policy, published in the Federal Register on July 8, 1977, allows a limited number of compounds, including methane, to be excluded from control actions. States have been advised that they should exclude these compounds from baseline emission inventories that are to be used for control strategy development for ozone.

Although motor vehicles are regulated directly by the Clean Air Act on a total hydrocarbon basis (rather than on a "reactive" hydrocarbon basis), it is appropriate, when estimating ozone levels, to consider only those motor vehicle emissions which will react to form ozone. However, consideration must be given to the format of any associated stationary source emission inventory so that mobile source and stationary source emission inventories are consistent in their exclusion.

20

For MOBILE4, as in MOBILE3, nonmethane emissions are estimated by subtracting methane offsets from the total hydrocarbon (THC) emissions. These offsets are constant. While the MOBILE4 computer program can calculate either total or nonmethane hydrocarbon (NMHC) emissions, all HC emission factors presented in this document are nonmethane hydrocarbons.

EPA's Office of Air Quality Planning and Standards has determined that volatile organic compounds (VOCs), which consist of any organic compounds that participate in atmospheric photochemical reactions, include all organic compounds except for those listed below:

methane
ethane
methyl chloroform
methylene chloride
trifluoromethane (FC-23)
trichlorofluoromethane (CFC-11)
dichlorodifluoromethane (CFC-22)
trichlorotrifluoroethane (CFC-113)
dichlorotetrafluoroethane (CFC-114)
chloropentafluoroethane (CFC-115)
dichlorotrifluoroethane (HCFC-123)
tetrafluoroethane (HFC-134a)
dichlorofluoroethane (HCFC-141b)
chlorodifluoroethane (HCFC-142b)

Of these compounds, only methane and ethane are represented in highway mobile source exhaust and evaporative hydrocarbon emissions. The emission factors presented in this supplement, whether for "total" or "non-methane" hydrocarbons, do not exclude ethane. Formaldehyde, which is a VOC under the definition given above, is not included in either the total or non-methane hydrocarbon emission factors presented in this supplement. Future revisions to the mobile source emission factor model and the AP-42 emission factor compilation document will account for these differences (i.e., after future revisions, ethane emissions will be excluded from the "non-methane" hydrocarbon emission factors and aldehyde emissions will be included in the "total" and "non-methane" hydrocarbon emission factors).

21

Chapter 1

LIGHT-DUTY GASOLINE-POWERED VEHICLES

1.A INTRODUCTION

Because of their widespread use, light-duty gasoline-powered vehicles (LDGVs), or automobiles, are responsible for a large share of air pollutant emissions in many areas of the United States. A LDGV is defined to be any gasoline-fueled vehicle designated primarily for transportation of persons and having a capacity of 12 or less persons. Substantial research effort has been expended to accurately characterize emissions from these vehicles. EPA's ongoing program to collect in-use vehicle emissions data was instituted a number of years ago in order to estimate their emission levels.

In addition to the methodologies presented for calculating the basic exhaust emission levels for HC, CO, and NO_x, data are referenced in this chapter for crankcase emissions, evaporative hydrocarbon emissions from vehicles that are parked (hot soak and diurnal), from vehicles that are in operation (running loss), and from vehicles that are being refueled, and emissions in the idle mode. Information is also given regarding the emission correction factors and travel weighting fractions.

All tables referenced in Chapters 1-8 are found in Appendix H. The first half of Appendix H applies to the low altitude region, the latter half to the high altitude region.

1.A.1 Test Procedure

LDGV exhaust and evaporative emissions testing is performed according to procedures stipulated in the Federal Register (42 FR 32954, June 28, 1977) and the Code of Federal Regulations (40 CFR Part 86, Subpart B, July 1, 1989). The basic test conditions under which LDGVs are tested are as follows:

1. Ambient temperature range is between 68° and 86°F.
2. Absolute humidity is adjusted to 75 grains of water per pound of dry air.
3. Average speed is 19.6 mph, including 18% idle operation.
4. Average percent of vehicle-miles-traveled (VMT) is 20.6% in cold start operation, 27.3% in hot start operation, and 52.1% in stabilized operation.

22

5. Average trip length is 7.5 miles.
6. Fuel volatility is 9.0 psi RVP.

Additional elements regarding the test procedure that are reflected in the emission estimates are as follows:

1. Air conditioning is not in use.
2. Car contains driver and passenger, with no additional passengers, luggage, etc.
3. Car is not pulling a trailer.

The test sequence for LDGVs is summarized below:

1. Determine the weight of the vehicle.
2. Determine the road-load (assuming level road, no curves, no wind), which is a function of weight and frontal area.
3. Precondition the vehicle (i.e., vehicle is briefly driven).
4. Place the vehicle in an ambient temperature environment between 68° and 86°F, with the engine off for at least 12 hours.
5. The fuel tank is drained and refilled to 40% full with the specified test fuel.
6. Move the vehicle (with the engine shut off) into the evaporative emission enclosure. Close and seal enclosure doors. Start diurnal heat build for one hour so that the fuel temperatures rise from 60 to 84°F. This is the diurnal breathing loss test.
7. Push the vehicle onto a dynamometer. Start the engine and begin collecting exhaust emissions.
8. Emissions for the first 505 seconds are collected for test segment #1. The mileage driven is 3.59 miles with an average speed of 26 mph. This is the cold start portion of the test.
9. Test segment #2 collects emissions for the next 870 seconds. The engine is not turned off between Steps 8 and 9. The mileage driven is 3.91 miles and the average speed is 16 mph. This is the stabilized portion of the test.
10. The engine is turned off, and remains off for 10 minutes.

23

11. The car is re-started. The first 505 seconds are re-run and emissions are collected for test segment #3. This is the hot start portion of the test.
12. The grams of each pollutant are determined for each test segment. NO_x emissions are adjusted for humidity. The exhaust emission levels, in grams per mile, are computed.
13. Place the vehicle inside the evaporative emission enclosure immediately after the test segment #3. Close and seal enclosure doors for 60 minutes. This is the hot soak test.

Running loss testing is performed by operating the vehicle over specified driving cycles on a dynamometer that is installed inside of an evaporative emissions enclosure. The test procedure, which has not been formally promulgated, is outlined below. Tests are conducted at different temperatures and using different RVP fuels to permit estimating running loss emission factors at different speeds and temperatures.

1. Drain and refill fuel tank to 40 percent full with Indolene test fuel (9.0 psi RVP).
2. Perform the following preconditioning sequence at 95°F: Drive one LA-4 cycle, one hour soak, drive another LA-4 cycle, one hour soak.
3. Drain vehicle fuel tank and refill to 40 percent full using the desired test fuel.
4. Operate the vehicle over another LA-4 driving cycle.
5. Vehicle soak for 12 to 30 hours at the desired test temperature.
6. Push the vehicle onto the dynamometer in the evaporative emission enclosure.
7. Drive the vehicle continuously for approximately one hour over the desired test cycle. (Test cycles used for running loss testing are the New York City Cycle and the LA-4. Running loss testing over the Highway Fuel Economy Test cycle was discontinued when it was observed that running loss emissions over that cycle are nearly nonexistent in almost all cases.) Six repetitions of the NYCC, or three repetitions of the LA-4, are required.
8. Repeat steps 3 thru 7 above as required to achieve a valid test at each desired combination of temperature and fuel volatility.

1.A.2 General Emissions Calculation Equations

The following generalized equations are used to calculate the LDGV emission factors (subscripts dropped from equations for clarity):

$$\text{COMPHC} = \text{SUM} \{ \text{TF} * [(\text{BEF} * \text{SALHCF} * \text{RVPCE}) + \text{REFUEL} + \text{RNGLOS} + \text{CCEVRT}] \}$$

$$\text{COMPco} = \text{SUM} [\text{TF} * (\text{BEF} * \text{SALHCF} * \text{RVPCE})]$$

$$\text{COMPNO} = \text{SUM} [\text{TF} * (\text{BEF} * \text{SALHCF})]$$

where:

$$\text{BEF}_{\text{HC}} = \{[(\text{BER} * \text{OMTCF}) - \text{OFFMTH}] * \text{PCLEFT}\} + \text{OMTTAM}$$

$$\text{BEF}_{\text{CO}} = (\text{BER} * \text{OMTCF} * \text{PCLEFT}) + \text{OFFCO} + \text{OMTTAM}$$

$$\text{BEF}_{\text{NO}} = (\text{BER} * \text{OMTCF}) + \text{OMTTAM}$$

$$\text{SALHCF}_{\text{HC}, \text{CO}} = \text{SCF} * \text{ACCF} * \text{XLCF} * \text{TWCF}$$

$$\text{SALHCF}_{\text{NO}} = \text{SCF} * \text{ACCF} * \text{XLCF} * \text{TWCF} * \text{HHH}$$

And also where:

COMPHC_n = The composite HC emission factors in g/mile, on January 1 of calendar year n.

SUM_i = The summation over twenty model years i, from n-19 to n, where n is the calendar year.

TF_i = The fraction of the total miles driven, for model year i, on January 1 of calendar year n.

BEFin = The basic exhaust emission rates in g/mi, for model year i, in calendar year n.

SALHCF_{ips} = The composite speed, air conditioning, extra load, and trailer towing correction factor, for model year i, pollutant p, and speed s.

RVPCE = The fuel volatility (as measured by Reid vapor pressure (RVP)) correction factor for exhaust emissions, for HC and CO emissions from model year 1971-79 vehicles.

REFUEL_i = The refueling HC emission factors in g/mi, for model year i.

25

RNGLOSi = The running loss HC emission factors in g/mi, for model year i.

CCEVRTi = The crankcase and g/mi evaporative HC emission factors, for model year i.

COMPCon = The exhaust CO emission factors in g/mile, on January 1 of calendar year n.

COMPNon = The exhaust NOx emission factors in g/mile, on January 1 of calendar year n.

BERipn = The basic nontampered exhaust emission rates in g/mile, for model year i, pollutant p, on January 1 of calendar year n.

OMTCFipt = The composite operating mode and temperature (and fuel volatility, if temperature is > 40°F and model year is 1980 or later) correction factor, for model year i, pollutant p, at temperature t.

OFFMTHi = The methane offsets in g/mi, for model year i, if nonmethane HC emissions are being estimated.

PCLEFTipn = The exhaust emission benefit of an operating inspection and maintenance (I/M) program for model year i, pollutant p, in calendar year n.

OMTTAMipn = The emission offsets in g/mi corrected for temperature and operating mode, for model year i, pollutant p, in calendar year n, due to all types of tampering.

OFFCOit = The bag 1 CO offsets in g/mi corrected for operating mode, for model year i, at temperature t.

SCFips = The speed correction factor, for model year i, pollutant p, at speed s.

ACCFi = The air conditioning correction factor for model year i.

XLCFi = The extra load correction factor for model year i.

TWCFi = The trailer towing correction factor for model year i.

HHH = The humidity correction factor (for NOx emissions only).

The general equations for estimating hot stabilized idle emissions are as follows:

$$IEF = \text{SUM} [TF * (IER - IDLMTH + TAMPIDL)]$$

where:

IEFn = The idle emission factors in g/hour, for pollutant p, in calendar year n.

IERNp = The idle emission rates in g/hour, for model year i, pollutant p, in calendar year n.

IDLMTHi = The idle methane offsets in g/hour, for model year i, applicable only to HC emissions, if nonmethane HC emissions are being estimated.

TAMPIDLInp = The idle emission rates in g/hour, for model year i, pollutant p, in calendar year n, due to tampering.

Note that idle emissions are not corrected for temperature or operating mode.

1.8 EMISSIONS

This section discusses the emission estimates for the LDGVs: basic exhaust emission rates, emission rates including tampering, crankcase emissions, other evaporative HC emission components, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.1 of Appendix A. The emissions reflect vehicles which have received typical in-use maintenance. Further, the vehicles are not involved in an I/M or anti-tampering program.

1.8.1 Basic Exhaust Emission Rates

The basic exhaust emission rates for LDGVs were derived from data on in-use vehicles, tested with fuel volatility at the certification level (9.0 psi RVP), with no observed tampering. The assumption in the derivation of the basic exhaust emission rates is that emission levels change linearly as vehicles accumulate mileage. The emission rates are dependent upon three variables:

1. zero mile emission levels,
2. emission deterioration rates for vehicles with 50,000 miles or less accumulated mileage, and,
3. emission deterioration rates for vehicles with more than 50,000 accumulated miles.

The zero-mile emission levels are the average grams of pollutants emitted by the vehicles at zero miles. The two emission deterioration rates adjust the zero mile levels as vehicles accumulate mileage. Note that for pre-1981 model year HC and CO emissions and all model year NO_x emissions, the same emission deterioration rates are used at all mileages.

The basic exhaust emission levels are calculated from a two-step linear function:

$$\begin{aligned} \text{BER}_{ipn} &= \text{ZML}_{ip} + \text{DR}_{lip} * \text{Min} && \text{if } M \leq 50,000 \text{ miles} \\ &= \text{ZML}_{ip} + \text{DR}_{lip} * 5.0 + \text{DR2}_{ip} * (\text{Min} - 5.0) && \text{if } M > 50,000 \text{ miles} \end{aligned}$$

where the lower case letters are subscripts and

BER_{ipn} = The nontampered basic exhaust emission levels in g/mile, for model year i and pollutant p, on January 1 of calendar year n.

ZML_{ip} = The zero mile emission levels in g/mile, for model year i and pollutant p.

DR_{lip} = The emission deterioration rates for vehicles with less than or equal to 50,000 miles, in (g/mile)/10,000 miles, for model year i and pollutant p.

DR2_{ip} = The emission deterioration rates for vehicles with more than 50,000 miles, in (g/mile)/10,000 miles, for model year i and pollutant p. Note that for pre-1981 model year HC and CO emissions, and all model year NO_x emissions, DR2 equals DR1.

Min = The model year i cumulative mileage divided by 10,000 miles, on January 1 of calendar year n.

The basic nontampered exhaust emission rates are presented in Appendix H (Table 1.1.1A) for the different LDGV model year groups and pollutants.

1.B.2 Exhaust Emission Rates With Tampering

Tampering offsets in g/mi are added to the basic exhaust emission rates so that the overall fleet emissions reflect national average rates of tampering. (Locality-specific tampering rates can be provided as part of the input stream by the MOBILE4 user having such information.) The methodologies used to estimate the tampering rates and the emission offsets from various types of vehicle tampering are described in Appendix E.

Tampering effects are first estimated for each type of tampering and operating mode (cold start, stabilized, and hot start), as described in the following equation:

$$\text{TAMPOFFipmn} = \text{TAMPipm} * \text{PEQUIPim} * \text{RATEimn}$$

where:

TAMPOFFipmn = The emission offsets due to tampering in g/mi, for model year i, pollutant p, tampering type m, in calendar year n.

TAMPipm = The increase in emissions from tampered vehicles in g/mi, for model year i, pollutant p, and tampering type m.

PEQUIPim = The percent of the model year i vehicles that are equipped with item m that can be tampered with.

RATEimn = The percent of model year i vehicles with equipment m that has been tampered with in calendar year n.

The emission offsets of each type of tampering are then combined to form overall tampering offsets for cold start, stabilized, and hot start operating modes. They are then corrected for temperature, and combined by the following equation:

$$\begin{aligned}\text{OMTTAMipn} &= (\text{TAMPOFFipn1} * \text{CS} * \text{TCF1}) + (\text{TAMPOFFipn2} * \text{ST} * \text{TCF2}) \\ &\quad + (\text{TAMPOFFipn3} * \text{HS} * \text{TCF3})\end{aligned}$$

where:

OMTTAMipn = The composite tampering offsets in g/mi, for model year i, pollutant p, in calendar year n.

TAMPOFFipn = The tampering offsets in g/mi, for model year i, pollutant p, in calendar year n, for each of the operating modes (cold start, stabilized, hot start).

CS = Percent of VMT accumulated in cold start mode.

ST = Percent of VMT accumulated in stabilized mode.

HS = Percent of VMT accumulated in hot start mode.

TCF = Temperature correction factor (or temperature and fuel volatility correction factor, depending on model year group) for each of the operating modes.

The exhaust emission rates including tampering in g/mi are presented in Appendix H, Table 1.1.1B, for the different LDGV model year groups and pollutants at different mileage intervals.

1.B.3 Crankcase and Evaporative HC Emission Levels

In addition to the basic exhaust HC emission levels and tampering offsets, five evaporative HC emission components are also calculated by MOBILE4:

1. Crankcase HC emissions are evaporative emissions coming from the crankcase when the engine is running.
2. Hot soak losses are produced as fuel evaporates from either the carburetor system (carbureted vehicles) or the fuel tank (fuel-injected vehicles) at the end of a trip.
3. Increases in ambient temperature result in expansion of the air-fuel mixture in a partially filled fuel tank and the generation of additional fuel vapor. As a result, diurnal emissions are expelled into the atmosphere.
4. Running loss emissions are evaporative emissions generated when the vehicle is operating.
5. Refueling emissions are evaporative emissions resulting from either displacement of gasoline vapor from the vehicle fuel tank or spillage of fuel when the vehicle is being refueled.

Note that the first three emission components (crankcase, hot soak, and diurnal) are sometimes called "crankcase and g/mi evaporative HC emissions," a terminology carried over from MOBILE2/MOBILE3. The last two emission components are new additions in MOBILE4.

The evaporative emissions are calculated according to the following three equations:

$$\begin{aligned} \text{CCEVRT}_i &= [(HS + TAMPHS) * TPD + (DI + TAMPDI)] / MPD + \\ &\quad (CC + TAMPC) \\ \text{RNGLOS} &= RULLOSS + TAMPR \\ \text{REFUEL} &= (DISP + SPILL) / ROADFE \end{aligned}$$

where:

CCEVRT_i = The sum of crankcase and g/mi evaporative HC emission factors, for model year i.

HStki = The hot soak emission rates in g/trip, corrected for temperature t and fuel of k psi RVP, for model year i.

TAMPHSkin = The hot soak excess emission rates in g/trip, corrected for k psi RVP fuel volatility, model year i, in calendar year n due to tampering.

TPDj = The trips per day values for age j vehicles.

DITki = The diurnal emission rates in grams, corrected for temperature t, k psi RVP fuel volatility, and model year i.

TAMPDITkin = The diurnal excess emission rates in grams, corrected for temperature t, k psi RVP fuel volatility, model year i, in calendar year n due to tampering.

MPDj = The miles per day values for age j vehicles.

CCi = Crankcase emissions in g/mi, for model year i.

TAMPCCin = The crankcase excess emissions in g/mi, for model year i, in calendar year n due to PCV tampering.

RNGLOSi = The running loss HC emission factors in g/mi, for model year i.

RULOSStki = The running loss emission rates in g/mi, corrected for temperature t, k psi RVP fuel volatility, and model year i.

TAMPRLtkin = The running loss excess emission rates in g/mi, corrected for temperature t, k psi RVP fuel volatility, model year i, in calendar year n due to tampering.

REFUELi = The refueling emission factors in g/mi, for model year i.

DISPk = The displacement refueling losses in g/gallon, corrected for k psi RVP fuel volatility.

SPILL = An average spillage rate in g/gallon.

ROADFEi = Road fuel economy, in gallons/mi, for model year i vehicles.

Except for the crankcase and refueling HC emissions, all other evaporative HC emission components are modeled as direct functions of ambient temperature and fuel volatility. (Refueling emissions are adjusted in MOBILE4 on the basis of the specified ASTM fuel volatility class, which serves as a surrogate variable for the effects of both ambient temperature and fuel volatility on these emissions.) In MOBILE4, it is assumed that there are no hot soak, diurnal, running loss, or refueling emissions when the temperature is less than or equal to 40°F. Further, except for crankcase and refueling emissions, these evaporative HC emissions, as can be seen from the above equations, are corrected for fuel volatility and temperature.

Under FTP conditions, the diurnal emissions are measured during a heat rise from 60° to 84°F over a one hour period. The hot soak emissions are measured immediately at the end of the hot start (test segment #3) portion of the exhaust emissions testing, with the ambient temperature about 82°F. The fuel tank level is at 40%, with fuel at the designated fuel volatility levels.

The LDGV crankcase, hot soak, and diurnal emissions at both 9.0 and 11.5 psi RVP fuels from nontampered vehicles tested under FTP conditions are summarized in Table 1.1.2A of Appendix H. The combined crankcase and g/mi evaporative HC emission tampering offsets at various mileage intervals are presented in Table 1.1.2B. The nontampered running loss emissions by model year group, fuel volatility level, and ambient temperature are summarized in Table 1.1.2C. The refueling emissions by model year are given in Table 1.1.2D.

1.B.4 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.1.11A through 1.1.11C of Appendix H for HC, CO, and NO_x, respectively. The HC emission levels reflect nonmethane HC emissions, and include crankcase and four other evaporative HC emission components (hot soak, diurnal, running loss, and refueling emissions). Also, all emission rates include tampering.

1.B.5 Hot Stabilized Idle Emission Rates

Estimates of emissions from the automotive fleet during a vehicle's idle operating mode have become more of a concern in transportation control plans, environmental impact statements, and state implementation plans. Examples of extended idle time are waits at shopping centers, airports, sport complexes, and with business drive-in window services. The emission estimates presented in this section reflect engines operating in a hot stabilized condition.

32

The idle emission rates are expressed in units of grams per hour, as opposed to the exhaust and other emission rates which are in units of grams per mile. For NO_x emissions and pre-1977 model year HC and CO emissions, the LDGVs idle emission levels are calculated from the zero mile idle emission levels and idle emission deterioration rates. The HC and CO idle emission rates for 1977 and later model year LDGVs are calculated from the hot portions (hot stabilized and hot start) of the FTP exhaust emissions. The g/hr idle emission levels by model year and pollutant at three mileage points (zero, 50,000, and 100,000 miles), are given in Table 1.1.3 of Appendix H.

1.C TRAVEL WEIGHTING FRACTIONS

The LDGV travel weighting fractions are the individual model year proportions of the total LDGV VMT. To generate the travel weighting fractions, three distributions are required:

1. annual mileage accumulation rate distribution,
2. registration distribution, and,
3. diesel sales distribution.

The travel weighting fractions in this document reflect a January 1 evaluation date. For the LDGVs, the model year is assumed to begin sales on the October 1 preceding the corresponding calendar year. Further, it is assumed that the vehicles are sold and accumulate mileage according to a uniform distribution. These assumptions permit the estimation of the January 1 fleet mileage accumulation rate distribution and the January 1 registration distribution from July 1 information. An example of the travel weighting fraction calculation based on calendar year of 1988 is given in Appendix H (Table 1.1.5, using the information provided in Table 1.1.4A).

1.C.1 Annual Mileage Accumulation Rate Distribution

A given vehicle is assumed to travel according to the annual mileage accumulation distribution given in the third column of Table 1.1.4A. For example, at a uniform rate, the vehicle travels 13,118 miles in its first year, 12,408 miles in its second year, and 4,562 miles in its 20th year.

The January 1 mileage accumulation rate distribution is derived from the annual mileage accumulation rate distribution for individual vehicles. This derivation averages out the effects of purchase date. The derivation is described in Appendix D, and the resulting distribution is given in the fifth column of Table 1.1.4A.

1.C.2 Registration Distribution

The second column of Table 1.1.4A also presents the estimated LDGV registration distribution fractions. These fractions are the individual model year proportions of the entire LDV fleet (both gasoline and diesel powered vehicles combined). The registration distribution is based on July 1 information and is transformed to January 1 figures according to the procedure described in Appendix D. The January 1 LDGV fleet registration distribution is presented in the fourth column of Table 1.1.4A.

1.C.3 Diesel Sales Distribution

The diesel sales distribution is used in the travel weighting fractions to account for the influx of diesels. The diesel sales fractions for the light-duty vehicles (LDDVs) are given in Table 1.5.4B. For example, prior to 1978, diesels are considered to be an insignificant proportion of the LDV fleet (less than 0.5 percent). The distribution is anticipated to stabilize in model year 1995, with about 95 percent of the LDV sales being gasoline-powered vehicles.

1.C.4 Trips per Day and Miles per Day Estimates

Two other parameters related to vehicle travels are the trips per day and miles per day estimates. These estimates are used to calculate g/mi evaporative HC emissions from g/trip hot soak and grams diurnal emission rates. Both of these parameters are functions of vehicle age. The miles per day estimates are the January 1 mileage accumulation rates (column D of Table 1.1.5) divided by 365 days.

Trips per day and miles per day distributions by vehicle age are given in Table 1.1.4C.

1.D EMISSION CORRECTION FACTORS

The LDGV basic exhaust emission levels are based on test results under the standardized conditions defined in Section 1.A.1. However, the basic exhaust emission levels are affected by ambient and vehicle usage conditions which differ from the prescribed test procedure. The conditions under which emissions are known to vary are the average speed, fuel volatility level, ambient temperature, fraction of VMT in cold and hot start operating modes, use of air conditioning, carrying of an extra load, trailer towing, and humidity. Emission correction factors are available to compensate for variations in these conditions.

1.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a driving cycle with an average speed of 19.6 mph. For situations where the average speed of the vehicle deviates from this value, a speed correction factor is applied.

The speed correction factor is symbolized as SCF_{ipsxw}, where the lower case letters are subscripts and,

SCF_{ipsxw} = The speed correction factor for model year i, pollutant p, at average speed s. This is normalized to the speed associated with a cold start mode VMT fraction x and a hot start mode VMT fraction w.

The user is cautioned that this correction factor is only valid for speeds in the 2.5 through 55 mph range, since the regression equations were based on speed data in that range. Extrapolations to speeds beyond this range should not be made.

The coefficients for the speed correction factors, by model year and pollutant, are given in Tables 1.1.6A for pre-1977 model years, and 1.1.6B for 1977 and later model years.

1.D.2 Fuel Volatility Correction Factor

The volatility, as measured by Reid Vapor Pressure (RVP), of commercially available fuel for in-use vehicles had been increasing since 1970, from the level used for certification (9.0 psi) to about 11.5 psi in most of the country during the summer season in the mid to late 1980s. EPA's Emission Factor data collected at three fuel volatility levels (9.0, 10.4, and 11.5 psi RVP) showed that high volatility fuels produce higher evaporative and exhaust emissions. For evaporative HC emissions, fuel volatility is one of the parameters used in the model (as discussed in Section 1.B.3). For exhaust emissions at fuel volatility levels other than 9.0 psi RVP and when the ambient temperature is greater than 40°F, an RVP correction factor is used for 1971 and later model year vehicles.

There are three fuel volatility correction factor models used for exhaust emissions for temperatures above 40°F in MOBILE4:

1. For model years 1971-79, simple linear correction factors are used and are applied to exhaust HC and CO emissions only. The equations are:

$$RVPCF_{HC} = (0.56222 + 0.012512 * RVP) / 0.67483$$

$$RVPCF_{CO} = (7.1656 + 0.33413 * RVP) / 10.17277$$

where:

$RVPCF_k$ = The fuel volatility correction factor for k psi fuel.

RVP = The fuel volatility level in k psi RVP,

and the denominators are the value of the respective numerators evaluated at 9.0 psi RVP. These correction factors apply to the composite emission levels.

2. For 1980 and later model years and at temperatures greater than 75°F, the fuel volatility correction factor is combined with the high temperature correction factor, to be discussed in Section 1.D.4.
3. For 1980 and later model years at temperatures greater than 40°F but less than or equal to 75°F, two steps of correction are required. First, a RVP correction at 75°F ($RVPCF_{k,75}$) is determined from the combined fuel volatility and high temperature correction factor model (from Section 1.D.4). Then, the following equation is used:

$$RVPCF_{kt} = 1.0 + \{(RVPCF_{k,75} - 1.0) * [(T - 40.0) / 35.0]\}$$

where:

$RVPCF_{kt}$ = The fuel volatility and high temperature correction factor, for k psi RVP fuel at temperature t (between 40 and 75°F).

$RVPCF_{k,75}$ = The fuel volatility and high temperature correction factor, for k psi RVP fuel at 75°F.

T = The ambient temperature in degrees Fahrenheit, which is between 40° and 75°F.

For 1980 and later model year vehicles, there are separate correction factors for fuel volatility for each test segment (bags 1, 2, 3). The fuel volatility correction factors for 1980 and later model year vehicles are also dependent on the fuel delivery system (carbureted, throttle-body fuel injection (TBI), or multi-point fuel injection (PFI)).

1.D.3 Low Temperature Correction Factor

The LDGV emission test procedure requires an ambient temperature between 68° and 86°F. A reference temperature of 75°F is used in MOBILE4. For temperatures lower than 75°F, a low temperature correction factor is needed. There are two low temperature correction factor models in MOBILE4:

1. The multiplicative model is applicable to all pollutants and test segments, except for the 1980 and later model years bag 1 (cold start) CO emissions. The equational form is as follows:

$$TCFipbt = EXP [TCipb * (T - 75.0)]$$

where the lower case letters are subscripts and

TCFipbt = The low temperature correction factor for model year i, pollutant p, test segment b, at ambient temperature t (< 75°F).

EXP = The exponential function.

TCipb = The temperature correction factor coefficient for model year i, pollutant p, test segment b.

T = Ambient temperature in degrees Fahrenheit.

2. An additive (or offset) model is used for 1980 and later model years bag 1 CO emissions:

$$OFFCOit = TCi * (T - 75.0)$$

where:

OFFCOit = The bag 1 CO offset in g/mi, for model year i, at temperature t (< 75°F).

TCi = The bag 1 CO temperature correction factor coefficient for model year i.

The low temperature correction factor coefficients are presented in Table 1.1.7A.

1.D.4 High Temperature Correction Factor

For temperatures higher than 75°F, a correction factor is also needed to adjust the emission levels. A multiplicative model is used for each test segment and pollutant. There are two high temperature correction factor models used in MOBILE4:

1. For pre-1980 model years, the high temperature correction factor model is a function of temperature, similar to the low temperature correction factors described in the previous section.
2. For 1980 and later model years, a combined temperature and fuel volatility correction model is used:

$$\text{TRCFipbkt} = \text{EXP} [\text{RCipb} * (\text{RVP} - 9.0) + \text{TCipb} * (\text{T} - 75.0) \\ + \text{TRCipb} * (\text{RVP} - 9.0) * (\text{T} - 75.0)]$$

where the lower case letters are subscripts and

TRCFipbkt = The combined high temperature and fuel volatility correction factor, for model year i, pollutant p, test segment b, k psi RVP fuel, at ambient temperature t.

EXP = The exponential function.

RCipb = The fuel volatility correction factor coefficient, for model year i, pollutant p, test segment b.

RVP = The fuel volatility level in k psi RVP.

TCipb = The high temperature correction factor coefficient, for model year i, pollutant p, test segment b.

T = Ambient temperature in degrees Fahrenheit.

TRCipb = The combined high temperature and fuel volatility correction factor coefficient, for model year i, pollutant p, test segment b.

The high temperature correction factor coefficients are presented in Appendix H, Table 1.1.7B.

1.D.5 Temperature/Operating-Mode Correction Factor

For all conditions except where the CO offset model is in effect, a single emission correction factor called OMTCF adjusts for temperature (and fuel volatility) and hot stabilized/cold start operating-mode conditions that differ from the basic test procedure. Vehicles usually emit more emissions in a cold start mode than in a stabilized or a hot start mode. Also, vehicles emit more emissions after an extended engine off period than vehicles that have not set long enough to be in the cold start mode. As a result, the operating mode is a necessary element of this correction factor.

An integral part of the operating mode portion of OMTCF are the normalized bag fractions. The normalized bag fractions adjust OMTCF for emissions attributable to each operating mode. These fractions for LDGVs are given in Table 1.1.7C.

The OMTCF correction factor is defined as follows:

$$\text{OMTCFiptwxn} = [(\text{TERM1} + \text{TERM2} + \text{TERM3}) / \text{DENOM}]$$

where:

```
TERM1 = W * TCFipt * (Bip1 + DRlip1 * Min)
        if M ≤ 50,000 miles
        = W * TCFipt * [Bip1 + DRlip1 * 5.0 + DR2ipl * (Min-5.0)]
        if M > 50,000 miles

TERM2 = (1.0-W-X) * TCFip2t * (Bip2 + DRlip2 * Min)
        if M ≤ 50,000 miles
        = (1.0-W-X) * TCFip2t * [Bip2 + DRlip2 * 5.0 + DR2ip2 * (Min-5.0)]
        if M > 50,000 miles

TERM3 = X * TCFip3t * (Bip3 + DRlip3 * Min)
        if M ≤ 50,000 miles
        = X * TCFip3t * [Bip3 + DRlip3 * 5.0 + DR2ip3 * (Min-5.0)]
        if M > 50,000 miles

DENOM = Bip0 + DRlip0 * Min
        if M ≤ 50,000 miles
        = Bip0 + DRlip0 * 5.0 + DR2ip0 * (Min-5.0)
        if M > 50,000 miles
```

And also where:

OMTCFiptxn = The temperature operating-mode emission correction factor, for model year i, pollutant p, ambient temperature t, fraction of VMT in cold start operating mode w, and fraction of VMT in hot start operating mode x, on January 1 of calendar year n.

Bipb = The normalized bag fraction intercept coefficient, for model year i, pollutant p, and test segment b (test segment 0 is the entire basic test procedure).

DRlipb = The normalized bag fraction slope coefficient, for model year i, pollutant p, and test segment b (test segment 0 is the entire basic test procedure), for vehicles with less than or equal to 50,000 miles.

DR2ipb = The normalized bag fraction slope coefficient, for model year i, pollutant p, and test segment b (test segment 0 is the entire basic test procedure), for vehicles with greater than 50,000 miles. Note that for pre-1981 model year HC and CO emissions, and all model year NO_x emissions, DR2ipb equals DRlipb.

Min = The fleet cumulative mileage divided by 10,000 miles, for model year i on January 1 of calendar year n.

W = The fraction of VMT traveled in the cold start mode.

X = The fraction of VMT traveled in the hot start mode.

TCFipbt = The emission temperature correction factor, for model year i, pollutant p, test segment b, and at ambient temperature t.

For 1980 and later model years, when the temperature is less than 75°F and when the percent cold start is greater than zero, TCFipt is taken out of TERML. Then OMTCF reflects the temperature and operating mode correction factors for the stabilized and hot start operating modes, but only the operating mode correction factor for the cold start mode. The emissions of the cold start mode are corrected for temperature with the CO offset discussed in Section 1.D.3. This offset is multiplied by the percent of VMT in the cold start (W), correct for fuel volatility if temperature is over 40°F, and added to the basic emission rate, as presented in Section 1.A.2.

1.D.6 Air Conditioning Correction Factor

The LDGV emissions can be affected by the use of air conditioning. The air conditioning correction factor coefficients are based on data from vehicles tested at several different temperatures with the air conditioner on. These correction factors are given in Table 1.1.8A. The general correction factor equation is as follows:

$$\begin{aligned}
 ACCFipt &= U * Vi [Aip + Bip * (T - 75.0) - 1.0] + 1.0 \\
 U &= (DI - DIL0) / (DIHI - DILO) \\
 DI &= (DB + WB) * 0.4 + 15.0
 \end{aligned}$$

where the lower case letters are subscripts and

ACCFipt = The air conditioning correction factor for model year i, pollutant p, at ambient temperature t.

40

- U = The fraction of air conditioner-equipped vehicles that have the air conditioner in use, $0.0 \leq U \leq 1.0$.
 Vi = Fractions of the vehicles equipped with an air conditioner, for model year i. These fractions are given in Table 1.1.8B.
 Aip = The air conditioning correction factor intercept coefficient, for model year i and pollutant p.
 Bip = The air conditioning correction factor slope coefficient, for model year i and pollutant p.
 T = Ambient temperature in degrees Fahrenheit.
 DI = A discomfort index.
 DIL0 = The highest discomfort index where no air conditioners are in use (set to 70°F in MOBILE4).
 DILI = The lowest discomfort index where all the air conditioners are in use (set to 80°F in MOBILE4).
 DB = The dry bulb temperature in degrees Fahrenheit.
 WB = The wet bulb temperature in degrees Fahrenheit.

1.D.7 Extra Load Correction Factor

The basic exhaust emission rates are based on the "typical" vehicle weight with a driver and passenger, vehicle fuel, and other liquids. There are, however, situations in which vehicles are carrying significant extra weight due to additional passengers, luggage, etc. In these events, emissions are known to change.

To apply the vehicle extra load correction factor found in Table 1.1.8C to a specific situation, it is necessary for a user to have an estimate of the percentage of LDGV VMT accumulated with an additional 500 pounds. The correction factor for extra load is computed according to the following equation:

$$XLCF_{ip} = (XLC_{ip} - 1.0) * U + 1.0$$

where the lower case letters are subscripts and

$$XLCF_{ip} = \text{The extra load correction factor, for model year } i \text{ and pollutant } p.$$

- XLC_{ip} = The extra load correction factor coefficient, for model year i and pollutant p.
 U = The fraction of LDGV VMT accumulated with an extra load, $0.0 \leq U \leq 1.0$.

1.D.8 Trailer Towing Correction Factor

As with the extra load correction factor, the trailer towing correction factor will adjust LDGV emissions for usage conditions which differ from the basic test procedure. It has been determined that towing a trailer affects a vehicle's emissions. As such, a correction factor is available to adjust LDGV emissions when a trailer is being towed. The correction factor coefficients given in Table 1.1.8D are valid for a trailer weight of 1000 pounds. This correction factor is computed by the following equation:

$$TTCF_{ip} = (TTC_{ip} - 1.0) * U + 1.0$$

where the lower case letters are subscripts and

- $TTCF_{ip}$ = The trailer towing correction factor, for model year i and pollutant p.
 TTC_{ip} = The trailer towing correction factor coefficient, for model year i and pollutant p.
 U = The fraction of LDGV VMT accumulated while towing a trailer, $0.0 \leq U \leq 1.0$.

1.D.9 NO_x Humidity Correction Factor

The NO_x emission factors are normalized to 75 grains of water per pound of dry air. In order to adjust NO_x emissions to different humidity conditions, a multiplicative correction factor is available. The formula for the correction factor is given below, and is applicable for all model years:

$$HCF = 1.0 - 0.0038 * (H - 75.0)$$

where:

- HCF = The NO_x humidity correction factor.
 H = Humidity level in grains of water per pound of dry air, $20.0 \leq H \leq 140.0$.

43

Chapter 2

LIGHT-DUTY GASOLINE-POWERED TRUCKS I

2.A INTRODUCTION

This chapter presents the emission factors for light-duty gasoline-powered trucks (LDGTls) with a gross vehicle weight (GVW) rating of 6,000 pounds or less. Although LDGTls have a load carrying capability that exceeds that of passenger cars, they are often used for personal transportation and light hauling.

2.A.1 Test Procedure

The test procedure used for determining the LDGTl basic exhaust emissions is almost identical to the LDGV test procedure. The only difference between the two test procedures is the road-load horsepower setting. The summary of the LDGV test procedure in Chapter 1 is also applicable for LDGTls.

2.A.2 General Emissions Calculation Equations

The equations for LDGV emission calculations presented in Chapter 1 are also valid for the LDGTls, although the emissions, travel weighting fractions, and emission correction factors for LDGTls are different.

2.B EMISSIONS

This section discusses the LDGTl emission estimates: basic exhaust emission rates, emission rates including tampering, crankcase emissions, other evaporative HC emission components, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.2 of Appendix A. The emissions reflect trucks which have received typical in-use maintenance. Further, the trucks are not involved in an I/M or anti-tampering program.

The discussions of the different LDGV emissions in Chapter 1 are also valid for the LDGTls, with minor differences noted wherever applicable.

L

Preceding page blank

44

2.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for LDGT1s are calculated from two variables:

1. zero mile emission level, and,
2. emission deterioration rate at all mileages.

The LDGT1 basic exhaust emission rates by model year group and pollutant are given in Table 1.2.1A.

2.B.2 Exhaust Emission Rates With Tampering

Emission offsets in g/mi due to tampering are added to the basic exhaust emission rates so that the fleet emission rates reflect national average rates of tampering. The exhaust emission rates including tampering are presented in Table 1.2.1B for the different LDGT1 model year groups and pollutants at different mileage intervals.

2.B.3 Crankcase and Evaporative HC Emission Levels

The LDGT1 crankcase, hot soak and diurnal emissions at both 9.0 and 11.5 psi fuels from nontampered vehicles tested under FTP conditions are presented in Table 1.2.2A. The combined crankcase and g/mi evaporative HC emission tampering offsets at various mileage intervals are presented in Table 1.2.2B. The nontampered running loss emissions by model year group, fuel volatility level, and ambient temperature are summarized in Table 1.2.2C. The refueling emissions by model year are given in Table 1.2.2D.

2.B.4 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.2.11A through 1.2.11C for HC, CO, and NO_x, respectively. The HC emission levels reflect non-methane HC emissions, and include crankcase and four other evaporative HC emission components. All emission rates include tampering effects.

2.B.5 Hot Stabilized Idle Emission Rates

The LDGT1 hot stabilized g/hr idle emission rates are given in Table 1.2.3.

2.C TRAVEL WEIGHTING FRACTIONS

The LDGT1 travel weighting fractions are the individual model year proportions of the total LDGT1 VMT. To generate the travel weighting fractions, three distributions are required:

1. annual mileage accumulation rate distribution,
2. registration distribution, and,
3. diesel sales distribution.

The first and second distributions are given in Table 1.2.4, and the third distribution is given in Table 1.6.4B. More detailed information is available in Chapter 1 on these distributions.

The travel weighting fractions, as in LDGVs, reflect a January 1 evaluation date. For the LDGT1s, the model year is assumed to begin sales on the October 1 preceding the corresponding calendar year. Further, it is assumed that the trucks are sold and accumulate mileage according to a uniform distribution. These assumptions permit the estimation of the January 1 fleet mileage accumulation rate distribution and the January 1 registration distribution from July 1 information. An example of the travel weighting fraction calculation based on calendar year of 1988 is given in Table 1.2.5.

The trips per day and miles per day estimates for LDGT1s are given in Table 1.2.4C.

2.D EMISSION CORRECTION FACTORS

The LDGT1 basic exhaust emission levels are based on test results under the standardized conditions defined in Chapter 1. However, the basic exhaust emission levels are affected by ambient and truck usage conditions which differ from the prescribed test procedure. The conditions under which emissions are known to vary are the average speed, fuel volatility level, ambient temperature, fraction of VMT in cold and hot start operating modes, use of air conditioning, carrying of an extra load, trailer towing, and humidity level. Emission correction factors are available to compensate for variations in these conditions.

The LDGT1s correction factors are based on the LDGV information. Therefore, the LDGT1 correction factors are those from the LDGVs, and the LDGV discussions in Chapter 1 are valid for the LDGT1s.

2.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a driving cycle with an average speed of 19.6 mph. For those situations where the average speed of the truck deviates from this value, a speed correction factor is applied. The LDGT1 speed correction factors are given in Tables 1.2.6A for pre-1979 model years, and 1.2.6B for 1979 and later model years.

2.D.2 Fuel Volatility Correction Factor

For LDGT1 exhaust emissions at fuel volatility levels other than 9.0 psi RVP and at ambient temperatures greater than 40°F, an RVP correction factor is also used. The RVP correction factors for LDGT1s are the same as those used for LDGVs (described in Chapter 1, Section 1.D.2).

2.D.3 Low Temperature Correction Factor

For those situations where the ambient temperature is lower than 75°F, a low temperature correction factor is applied. Table 1.2.7A presents these correction factors for the LDGT1s. The bag 1 CO offset model is applied to 1984 and later model year LDGT1s.

2.D.4 High Temperature Correction Factor

For those situations where the ambient temperature is equal to or higher than 75°F, a high temperature correction factor is applied. Table 1.2.7B presents these correction factors for the LDGT1s.

2.D.5 Temperature/Operating-Mode Emission Correction Factor

As in LDGVs, a single emission correction factor called OMTCF adjusts for temperature and operating-mode conditions that differ from the basic test procedure. As described in Chapter 1, OMTCF depends on normalized bag fractions. The LDGT1 normalized bag fractions are given in Table 1.2.7C.

2.D.6 Air Conditioning Correction Factor

The LDGT1 emissions can be significantly affected by the use of air conditioning. These correction factors are given in Table 1.2.8A. The fractions of LDGT1s equipped with an air conditioner, by model year, are given in Table 1.2.8B.

2.D.7 Extra Load Correction Factor

The basic exhaust emission rates are based on the "typical" truck weight with a driver and passenger, fuel, and other liquids. There are, however, situations in which trucks are carrying significant extra weight due to additional passengers, luggage, etc. In these events, emissions are known to change.

To apply the truck extra load correction factor found in Table 1.2.8C to a specific situation, it is necessary for a user to have an estimate of the percentage of LDGT1 VMT accumulated with an additional 500 pounds.

2.D.8 Trailer Towing Correction Factor

As with the extra load correction factor, the trailer towing correction factor will adjust LDGT1 emissions for usage conditions which differ from the basic test procedure. The correction factor coefficients given in Table 1.2.8D are valid for a trailer weight of 1,000 pounds.

2.D.9 NO_x Humidity Correction Factor

The LDGT1 NO_x humidity correction factor equation is the same as the equation used for LDGVs.

49

Chapter 3

LIGHT-DUTY GASOLINE-POWERED TRUCKS II

3.A INTRODUCTION

This chapter presents the emission factors for light-duty gasoline-fueled trucks (LDGT2s) with a gross vehicle weight (GVW) rating between 6,001 and 8,500 pounds. This vehicle type is required since these trucks were classified as heavy-duty vehicles through the 1978 model year. Beginning with the 1979 model year, these trucks have been considered light-duty trucks.

In general, every LDGV section and subsection discussion in Chapter 1 is valid for this chapter.

3.A.1 Test Procedure

The test procedure used for determining the LDGT2 basic exhaust emissions is almost identical to the LDGV test procedure. The only difference between the two test procedures is the road-load horsepower setting. The LDGV test procedure summarized in Chapter 1 is also valid for the LDGT2s.

3.A.2 General Emissions Calculation Equations

The equations for LDGV emission calculations presented in Chapter 1 are also valid for the LDGT2s, although the emissions, travel weighting fractions, and emission correction factors for LDGT2s are different.

3.B EMISSIONS

This section presents the LDGT2 emission estimates: basic exhaust emission rates, emission rates including tampering, crankcase emissions, and other evaporative HC emission components, January 1 emission levels, and idle emission rates. The pre-1979 model year LDGT2s were considered heavy-duty vehicles; their emission standards are given in Section A.1.3 of Appendix A. The 1979 and later LDGT2 emission standards are given in Section A.1.2 of Appendix A. The emissions reflect trucks which have received typical in-use maintenance. Further, the trucks are not involved in an I/M or anti-tampering program.

Preceding page blank

50

3.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for LDGT2s are calculated from two variables:

1. zero mile emission levels, and,
2. emission deterioration rates for vehicles at all mileages.

The LDGT2 basic exhaust emission rates by model year group and pollutant are given in Table 1.3.1A.

3.B.2 Exhaust Emission Rates With Tampering

Emission offsets in g/mi due to tampering are added to basic exhaust emission rates so that the fleet emission rates reflect national average rates of tampering. The exhaust emission rates including tampering are presented in Table 1.3.1B for the different LDGT2 model year groups and pollutants at different mileage intervals.

3.B.3 Crankcase and Evaporative HC Emission Levels

The LDGT2 crankcase, hot soak and diurnal emissions at both 9.0 and 11.5 psi fuels from nontampered vehicles tested under FTP conditions are given in Table 1.3.2A. The combined crankcase and g/mi evaporative emission tampering offsets at various mileage intervals are shown in Table 1.3.2B. The nontampered running loss emissions by model year group, fuel volatility, and ambient temperature are summarized in Table 1.3.2C. The refueling emissions by model year are given in Table 1.3.2D.

3.B.4 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.3.11A through 1.3.11C for HC, CO, and NO_x, respectively. The HC emission levels reflect non-methane HC emissions, and include crankcase and four other evaporative HC emission components. All emission rates include tampering effects.

3.B.5 Hot Stabilized Idle Emission Rates

The LDGT2 hot stabilized g/hr idle emission rates are given in Table 1.3.3.

3.C TRAVEL WEIGHTING FRACTIONS

The LDGT2 travel weighting fractions are the individual model year proportions of the total LDGT2 VMT. To generate the travel weighting fractions, three distributions are required:

1. annual mileage accumulation rate distribution,
2. registration distribution, and,
3. diesels sales distribution.

The first and second distributions are given in Table 1.3.4A, and the third distribution is given in Table 1.6.4B. More detailed information is available in Chapter 1 on these three distributions.

The travel weighting fractions, as in LDGVs, reflect a January 1 evaluation date. For the LDGT2s, the model year is assumed to begin sales on the October 1 preceding the corresponding calendar year. Further, it is assumed that the trucks are sold and accumulate mileage according to a uniform distribution. These assumptions permit the estimation of the January 1 fleet mileage accumulation rate distribution and the January 1 registration distribution from July 1 information. An example of the travel weighting fraction calculation based on calendar year of 1988 is given in Table 1.3.5.

The trips per day and miles per day distributions by vehicle age are given in Table 1.3.4C.

3.D EMISSION CORRECTION FACTORS

The LDGT2 basic exhaust emission levels are based on test results under the standardized conditions defined in Chapter 1. However, the basic exhaust emission levels are affected by ambient and truck usage conditions which differ from the prescribed test procedure. The conditions under which emissions are known to vary are the average speed, fuel volatility level, ambient temperature, fraction of VMT in cold and hot start operating modes, use of air conditioning, carrying of an extra load, trailer towing, and humidity level. Emission correction factors are available to compensate for variations in these conditions.

The LDGT2 emission correction factors are based on the LDGV information. Therefore, the LDGT2 correction factors are those from the LDGVs, and the discussions in Chapter 1 are valid for the LDGT2s.

52

3.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a driving cycle with an average speed of 19.6 mph. For those situations where the average speed of the truck deviates from this value, a speed correction factor is applied. The LDGT2 average cycle speed emission correction factors are given in Tables 1.3.6A for pre-1979 model years, and 1.3.6B for 1979 and later model years.

3.D.2 Fuel Volatility Correction Factor

For LDGT2 exhaust emissions at fuel volatility levels other than 9.0 psi RVP and ambient temperatures greater than 40°F, an RVP correction factor is also used. The RVP correction factors for LDGT2s are the same as those used for LDGVs (described in Chapter 1, Section 1.D.2).

3.D.3 Low Temperature Correction Factor

For those situations where the ambient temperature is lower than 75°F, a low temperature correction factor is applied. Table 1.3.7A presents these correction factors for the LDGT2s. The bag 1 CO offset model is applied to 1984 and later model year LDGT2s.

3.D.4 High Temperature Correction Factor

For those situations where the ambient temperature is equal to or higher than 75°F, a high temperature correction factor is applied. Table 1.3.7B presents these correction factors for the LDGT2s.

3.D.5 Temperature/Operating-Mode Emission Correction Factor

As in LDGVs, a single emission correction factor called OMTCF adjusts for temperature and operating-mode conditions that differ from the basic test procedure. As described in Chapter 1, OMTCF depends on normalized bag fractions. The LDGT2 normalized bag fractions are given in Table 1.3.7C.

3.D.6 Air Conditioning Correction Factor

The LDGT2 emissions can be significantly affected by the use of air conditioning. These correction factors are given in Table 1.3.8A. The fractions of LDGT2s equipped with an air conditioner, by model year, are given in Table 1.3.8B.

3.D.7 Extra Load Correction Factor

The basic exhaust emission rates are based on the "typical" truck weight with a driver and passenger, fuel, and other liquids. There are, however, situations in which trucks are carrying significant extra weight due to additional passengers, luggage, etc. In these events, emissions are known to change.

To apply the truck extra load correction factor found in Table 1.3.8C to a specific situation, it is necessary for a user to have an estimate of the percentage of LDGT2 VMT accumulated with an additional 500 pounds.

3.D.8 Trailer Towing Correction Factor

As with the extra load correction factor, the trailer towing correction factor will adjust LDGT2 emissions for usage conditions which differ from the basic test procedure. The correction factor coefficients given in Table 1.3.8D are valid for a trailer weight of 1000 pounds.

3.D.9 NO_x Humidity Correction Factor

The LDGT2 NO_x humidity correction factor equation is the same equation used for LDGVs.

Chapter 4

HEAVY-DUTY GASOLINE-POWERED VEHICLES

4.A INTRODUCTION

This chapter presents the emission factors for the heavy-duty gasoline-powered vehicles (HDGVs). A HDGV is defined to be any gasoline-fueled motor vehicle designated primarily for the transportation of property and rated at more than 8,500 pounds gross vehicle weight (GVW), or designated primarily for transportation of persons and having a capacity of more than 12 persons.

4.A.1 Test Procedure

The HDGV basic exhaust emission rates are based on the engine dynamometer transient test procedure stipulated in the Federal Register (48 FR 52170, November 16, 1983) and the Code of Federal Regulations (40 CFR, Part 86, Subpart N, July 1, 1989). The basic test conditions under which the HDGVs are tested are as follows:

1. Ambient temperature range is between 68° and 86°F.
2. Absolute humidity is adjusted to 75 grains of water per pound of dry air.
3. Average speed is 20.0 mph, including 27% idle operation.
4. Average percent VMT is 14.3% in cold operation, 86.7% in hot operation.
5. Average trip length is 6.5 miles.

The test procedure for HDGVs is summarized below:

1. Generate the maximum torque vs. speed curve of the engine.
2. Precondition the engine with practice cycle runs.
3. With the engine off, let it sit for at least 12 hours between 68° and 86°F. An optional procedure is the forced cool-down procedure, whereby cool water is circulated through the engine's water coolant system (and/or air is directed onto the engine) until the engine oil is between 68° and 75°F.
4. Conduct the cold test. The estimated mileage is 6.5 miles with an average speed of 20.0 mph.

Preceding page blank

56

5. The engine is turned off, and remained off for 20 minutes.
6. Conduct the hot test, which is the same as the cold test.
7. Calculate the grams of pollutant and total brake horsepower-hour for each test cycle.
8. Correct NOx emissions to 75 grains of water per pound of dry air.
9. Calculate the basic exhaust emissions in grams per brake horsepower-hour (g/bhp-hr).

4.A.2 General Emissions Calculation Equations

To calculate the HDGV emission factors, the following generalized equations are used (subscripts dropped from equations for clarity):

$$\begin{aligned} \text{COMPHC} &= \text{SUM} \{ \text{TF} * [\text{REFUEL} + \text{RNGLOS} + \text{CCEVRT} + \text{SCF} * (\text{BEF} - \text{OFFMTH})] \} \\ \text{COMPCO} &= \text{SUM} (\text{TF} * \text{SCF} * \text{BEF}) \\ \text{COMPNO} &= \text{SUM} (\text{TF} * \text{SCF} * \text{BEF}) \end{aligned}$$

where:

$$\text{BEF} = \text{OMTTAM} * \text{BER} * \text{TCF}$$

And also where:

SCF_{ps} = The speed correction factor for HDGVs, for pollutant p, at speed s.

TCF_{pt} = The temperature correction factor (not operating mode-dependent), for pollutant p, at temperature t.

All other variables have the same definitions as for LDGVs.

4.B EMISSIONS

This section discusses the emission estimates for the HDGVs: basic exhaust emission rates, emission rates including tampering, crankcase emissions and other evaporative HC emission components, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.3 of Appendix A. The emissions reflect vehicles which have received typical in-use maintenance. Further, the vehicles are not involved in an I/M or anti-tampering program.

4.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for HDGVs are calculated from two variables:

1. zero mile emission levels, and,
2. emission deterioration rates for vehicles at all mileages.

The HDGV basic exhaust emission rates by model year groups and pollutant are given in Table 1.4.1A.

The conversion factors which are used to convert the emissions in g/bhp-hr to emissions in g/mi are updated from the previous versions of mobile source emission factors. These conversion factors are dependent on projected sales in the different weight classes of the heavy-duty gasoline-powered vehicles and their respective fuel economies. The HDGV conversion factors by model year are given in Table 1.4.10B.

4.B.2 Exhaust Emission Rates With Tampering

Tampering offsets in g/mi are added to basic exhaust emission rates so that the fleet emission rates reflect national average rates of tampering. The exhaust emission rates including tampering are presented in Table 1.4.1B for the different HDGV model year groups and pollutants at different mileage intervals.

4.B.3 Crankcase and Evaporative HC Emission Levels

The HDGV crankcase, hot soak and diurnal emissions at both 9.0 and 11.5 psi RVP fuels from nontampered vehicles tested under FTP conditions are given in Table 1.4.2A. The combined crankcase and g/mi evaporative emission tampering offsets at various mileage intervals are shown in Table 1.4.2B. The nontampered running loss emissions by model year group, fuel volatility, and ambient temperature are summarized in Table 1.4.2C. The refueling emissions by model year are given in Table 1.4.2D.

4.B.4 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.4.11A through 1.4.11C for HC, CO, and NO_x, respectively. The HC emission levels reflect non-methane HC emissions, and include crankcase and four other evaporative HC emission components. All emission rates include tampering.

58

4.B.5 Hot Stabilized Idle Emission Rates

The HDGV hot stabilized g/hr idle emission rates are given in Table 1.4.3.

4.C TRAVEL WEIGHTING FRACTIONS

The HDGV travel weighting fractions are the individual model year proportions of the total HDGV VMT. To generate the HDGV travel weighting fractions, two distributions are required:

1. annual mileage accumulation rate distribution, and,
2. registration distribution.

These two distributions are given in Table 1.4.4. More detailed information is available in Chapter 1 on these distributions.

The travel weighting fractions in this document reflect a January 1 evaluation date. For the HDGVs, the model years are assumed to begin sales on January 1. Further, it is assumed that the vehicles are sold and accumulate mileage according to a uniform distribution. The travel weighting fractions based on calendar year 1988 are given in Table 1.4.5.

Average trips per day and miles per day estimates are used for HDGVs. These average values are given in Table 1.4.2A.

4.D EMISSION CORRECTION FACTORS

The HDGV basic exhaust emission levels are based on test results under the standard conditions defined in Section 4.A.1. However, the basic exhaust emission levels are affected by ambient and vehicle usage conditions which differ from the prescribed test procedure. The conditions under which HDGV emissions are known to vary are the average speed, fuel volatility level, and ambient temperature. Emission correction factors are available to compensate for variations in these conditions.

4.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a transient engine cycle with an estimated speed of 20.0 mph. For those situations where the average speed of the vehicle deviates from this

value, a speed correction factor is applied. Two speed correction factor models are used in MOBILE4:

1. $SCF_{ps} = EXP (A_p + B_p * s + C_p * s^2)$ for HC and CO
2. $SCF_{ps} = A_p + B_p * s + C_p * s^2$ for NO_x

where:

SCF_{ps} = The speed correction factor, for pollutant p at average speed s.

EXP = The exponential function.

A_p = The speed correction factor intercept coefficient, for pollutant p.

B_p = The speed correction factor first order coefficient, for pollutant p.

C_p = The speed correction factor second order coefficient, for pollutant p.

The coefficients for the speed correction factor equations are given in Table 1.4.6. The speed correction factors are valid only for speeds in the 2.5 through 55 mph range.

4.D.2 Fuel Volatility Correction Factor

For HDGV exhaust emissions at fuel volatility levels other than 9.0 psi and at ambient temperatures greater than 40°F, an RVP correction factor is also used. The RVP correction factors for HDGVs are the same as those used for LDGVs (described in Chapter 1, Section 1.D.2).

4.D.3 Low Temperature Correction Factor

For situations where the ambient temperature is less than 75°F, a low temperature correction factor is applied. This low temperature correction factor differs slightly in form from the low temperature correction factor given in Chapter 1. The HDGV low temperature correction factor is for the entire transient test, as opposed to the LDGV low temperature correction factors for the individual test segments. The HDGV low temperature correction factor coefficients are given in Table 1.4.7A.

4.D.4 High Temperature Correction Factor

For those situations where the ambient temperature is equal to or higher than 75°F, a high temperature correction factor is applied. This high temperature correction factor also differs slightly in form from the high temperature correction factor given in Chapter 1. For pre-1985 model years, the high temperature correction factor model is a function of temperature, similar to the low temperature correction factors described in the previous section. For 1985 and later model years, a combined temperature and fuel volatility correction model is used. The HDGV high temperature correction factor is also applied to the entire transient test, as opposed to the LDGV high temperature correction factors for the individual test segments. Table 1.4.7B presents these correction factors for HDGVs.

Chapter 5

LIGHT-DUTY DIESEL-POWERED VEHICLES

5.A INTRODUCTION

This chapter presents the emission factors for light-duty diesel-powered vehicles (LDDVs). A LDDV is defined to be any diesel-powered automobile designated primarily for transportation of persons and having a capacity of 12 or less persons.

5.A.1 Test Procedure

The test procedure used for determining the LDDV basic exhaust emissions is identical to the LDGV test procedure, outlined in Chapter 1.

5.A.2 General Emissions Calculation Equations

The same LDGV emission calculation equations are used for LDDVs, with the exception that the OMTCF parameter does not include the temperature correction factors, to be discussed in Sections 5.D.2 and 5.D.3.

5.B EMISSIONS

This section discusses the LDDV emission estimates: basic exhaust emission rates, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.1 of Appendix A. The emissions reflect vehicles which have received typical in-use maintenance. Further, the vehicles are not involved in an I/M or anti-tampering program.

LDDVs are considered to have insignificant crankcase and all other evaporative HC emission components. Therefore, no evaporative emission factor estimates are given.

Also, diesel vehicles are not subject to the types of tampering that EPA gathers information on in its tampering surveys. Therefore, tampering offsets are not added to any diesel-powered vehicle emission factors.

With the exceptions listed above, the discussions of the different LDGV emissions in Chapter 1 are also valid for the LDDVs.

62

5.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for LDDVs are calculated from two variables:

1. zero mile emission level, and,
2. emission deterioration rate at all mileages.

The LDDV basic exhaust emission rates by model year group and pollutant are given in Table 1.5.1.

5.B.2 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.5.11A through 1.5.11C for HC, CO, and NO_x, respectively. The HC emission levels reflect non-methane HC emissions.

5.B.3 Hot Stabilized Idle Emission Rates

The LDDV hot stabilized g/hr idle emission rates are given in Table 1.5.3.

5.C TRAVEL WEIGHTING FRACTIONS

The LDDV travel weighting fractions are individual model year proportions of the total LDDV VMT. To generate the travel weighting fractions, three distributions are required:

1. annual mileage accumulation rate distribution,
2. registration distribution, and,
3. diesel sales distribution.

The first and second distributions are given in Table 1.5.4A, and the third distribution is given in Table 1.5.4B. More detailed information is available in Chapter 1 on these distributions.

The travel weighting fraction in this document reflect a January 1 evaluation date. For LDDVs, model year sales are assumed to begin on October 1 of the preceding calendar year. Further, it is assumed that the vehicles are sold and accumulate mileage according to a uniform distribution. These assumptions permit the estimation of the January 1 fleet mileage accumulation rate distribution and the January 1

registration distribution from July 1 information. An example of the travel weighting fraction calculation based on calendar year of 1988 is given in Table 1.5.5.

Since it is assumed that there are no evaporative emissions from LDDVs, no trips per day or miles per day estimates are required for calculation of LDDV emission factors.

5.D EMISSION CORRECTION FACTORS

The LDDV basic exhaust emission levels are based on test results under the standardized conditions defined in Chapter 1. However, the basic exhaust emission levels are affected by ambient and vehicle usage conditions which differ from the prescribed test procedure. The conditions under which LDDV emissions are known to vary are the average speed and the fraction of VMT in cold and hot start operating modes. Emission correction factors are available to compensate for variations in these conditions.

Emissions from LDDVs may be somewhat dependent on temperature, but that dependence is thought to be relatively insignificant. Also, EPA has no data to quantify the effect of temperature on LDDV emissions. Therefore, no temperature correction factor is used for LDDVs.

The use of air conditioning, carrying of an extra load, trailer towing, humidity, and fuel volatility levels may affect LDDV emissions, but no information is available to estimate the effects.

5.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a driving cycle with an average speed of 19.6 mph. For those situations where the average speed of the vehicle differs from this value, a speed correction factor is applied.

The LDDV speed correction factor equation and coefficients are given in Table 1.5.6. The user is cautioned that the correction factor as given in Table 1.5.6 is only valid for speeds in the 2.5 through 55 mph range. Extrapolations to speeds beyond this range should not be made.

5.D.2 Speed/Operating-Mode Emission Correction Factor

A single emission correction factor called OMTCF adjusts for speed and operating-mode conditions that differ from the basic test procedure. As described in Chapter 1, OMTCF depends on normalized bag fractions. The LDDV normalized bag fractions are given in Table 1.5.7.

65

Chapter 6

LIGHT-DUTY DIESEL-POWERED TRUCKS

6.A INTRODUCTION

This chapter presents the emission factors for light-duty diesel-powered trucks (LDDTs). A LDDT is defined to be any diesel-powered motor vehicle designed primarily for transportation of property and rated at 8,500 pounds or less gross vehicle weight (GVW).

6.A.1 Test Procedure

The test procedure used for determining the LDDT basic exhaust emissions is almost identical to the LDGV test procedure. The only difference between the two test procedures is the road-load horsepower setting. The summary of the LDGV test procedure in Chapter 1 is also applicable for LDDTs.

6.A.2 General Emissions Calculation Equations

The same LDGV emission calculation equations are used for LDDTs, with the exception that the OMTCF parameter does not include the temperature correction factors, to be discussed in Sections 6.D.2 and 6.D.3.

6.B EMISSIONS

This section discusses the LDDT emission estimates: basic exhaust emission rates, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.2 of Appendix A. Prior to the 1978 model year, the number of LDDTs are considered insignificant. As a result, no emissions are measured prior to January 1, 1978. The emissions also reflect trucks which have received typical in-use maintenance. Further, the trucks are not involved in an I/M or anti-tampering program.

LDDTs, like LDDVs, are considered to have insignificant crankcase and all other evaporative HC emission components. Therefore, no evaporative emission factor estimates are given.

Also, diesel trucks are not subject to the types of tampering that EPA gathers information on in its tampering surveys. Therefore, tampering offsets are not added to any diesel-powered truck emission factors.

66

Preceding page blank

With the exceptions listed above, the discussions of the different LDGV emissions in Chapter 1 are also valid for the LDDTs.

6.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for LDDTs are calculated from two variables:

1. zero mile emission level, and,
2. emission deterioration rate at all mileages.

The LDDT basic exhaust emission rates by model year group and pollutant are given in Table 1.6.1.

6.B.2 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.6.11A through 1.6.11C for HC, CO, and NO_x, respectively. The HC emission levels reflect non-methane HC emissions.

6.B.3 Hot Stabilized Idle Emission Rates

The LDDT hot stabilized g/hr idle emission rates are given in Table 1.6.3.

6.C TRAVEL WEIGHTING FRACTIONS

The LDDT travel weighting fractions are the individual model year proportion of the total LDDT VMT. To generate the travel weighting fractions, three distributions are required:

1. annual mileage accumulation rate distribution,
2. registration distribution, and,
3. fleet diesel sales distribution.

The first and second distributions are given in Table 1.6.4A, and the third distribution is given in Table 1.6.4B. More detailed information is available in Chapter 1 on these distributions.

The travel weighting fractions in this document reflect a January 1 evaluation date. For LDDTs, model year sales are assumed to begin on October 1 of the preceding calendar year. Further, it is assumed that the trucks are sold and accumulate mileage according to a uniform distribution. These assumptions permit the estimation of the January 1 fleet mileage accumulation rate distribution and the January 1 registration distribution from July 1 information. An example of the travel weighting fraction calculation based on calendar year of 1988 is given in Table 1.6.5.

Since it is assumed that there are no evaporative emissions from LDDTs, no trips per day or miles per day estimates are required for calculation of LDDT emission factors.

6.D EMISSION CORRECTION FACTORS

The LDDT basic exhaust emission levels are based on test results under the standardized conditions defined in Chapter 1. However, the basic exhaust emission levels are affected by ambient and truck usage conditions which differ from the prescribed test procedure. The conditions under which LDDT emissions are known to vary are the average speed and the fraction of VMT in cold and hot start operating modes. Emission correction factors are available to compensate for variations in these conditions.

Emissions from LDDTs may be somewhat dependent on temperature, but that dependence is thought to be relatively insignificant. Also, EPA has no data to quantify the effect of temperature on LDDT emissions. Therefore, no temperature correction factor is used for LDDTs.

The use of air conditioning, carrying of an extra load, trailer towing, humidity, and fuel volatility levels may affect LDDT emissions, but no information is available to estimate the effects.

6.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a driving cycle with an average speed of 19.6 mph. For those situations where the average speed of the truck differs from this value, a speed correction factor is applied.

The LDDT speed correction factor equation and coefficients are given in Table 1.6.6. The user is cautioned that this correction factor is only valid for speeds in the 2.5 through 55 mph range. Extrapolations to speeds beyond this range should not be made.

68

6.D.2 Temperature/Operating-Mode Emission Correction Factor

A single emission correction factor called OMTCF adjusts for speed and operating-mode conditions that differ from the basic test procedure. As described in Chapter 1, OMTCF depends on normalized bag fractions. The LDDT normalized bag fractions are given in Table 1.6.7.

Chapter 7

HEAVY-DUTY DIESEL-POWERED VEHICLES

7.A INTRODUCTION

This chapter presents the emission factors for heavy-duty diesel-powered vehicles (HDDVs). An HDDV is defined to be any diesel-powered motor vehicle designated primarily for the transportation of property and rated at more than 8,500 pounds of gross vehicle weight (GVW). Supplementary emission factors for diesel transit buses are found in Appendix N.

7.A.1 Test Procedure

The test procedure used for determining the HDDV basic exhaust emissions is almost identical to the HDGV test procedure. The only difference between the two test procedures is the test cycle. The specific differences are as follows:

1. The average speed is 20.0 mph, with 36% idle operation.
2. The average trip length is 6.4 miles.
3. NO_x emissions are not corrected for humidity.

7.A.2 General Emissions Calculation Equations

The HDDV emission equations are:

$$\text{COMPHC} = \text{SUM} [\text{TF} * \text{SCF} * (\text{BER} - \text{OFFMTH})]$$

$$\text{COMPCO} = \text{SUM} (\text{TF} * \text{SCF} * \text{BER})$$

$$\text{COMPNO} = \text{SUM} (\text{TF} * \text{SCF} * \text{BER})$$

where:

SCF_{ps} = The speed correction factor for HDDVs, for pollutant p, at speed s.

All other variables have the same definitions as for LDGVs.

7.B EMISSIONS

This section discusses the emission estimates for HDDVs: basic exhaust emission rates, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.4 of Appendix A. The emissions reflect vehicles which have received typical in-use maintenance. Further, the vehicles are not involved in an I/M or anti-tampering program.

HDDVs are considered to have insignificant crankcase and all other evaporative HC emission components. Therefore, no evaporative emission factor estimates are given.

Also, heavy-duty diesel vehicles are not subject to the types of tampering that EPA gathers information on in its tampering surveys. Therefore, tampering offsets are not added to any diesel-powered vehicle emission factors.

With the exceptions listed above, the discussions of the different LDGV emissions in Chapter 1 are also valid for the HDDVs.

7.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for HDDVs are calculated from two variables:

1. zero mile emission level, and,
2. emission deterioration rate at all mileages.

The HDDV basic exhaust emission rates by model year group and pollutant are given in Table 1.7.1.

The conversion factors which are used to convert the emissions in g/bhp-hr to emissions in g/mi are updated from the previous versions of mobile source emission factors. These conversion factors are dependent on projected sales in the different weight classes of the heavy-duty diesel vehicles and their respective fuel economies. The HDDV conversion factors are given in Table 1.7.10B.

7.B.2 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.7.11A through 1.7.11C for HC, CO, and NO_x, respectively. The HC emission levels reflect non-methane HC emissions.

7.B.3 Hot Stabilized Idle Emission Rates

The HDDV hot stabilized g/hr idle emission rates are given in Table 1.7.3.

7.C TRAVEL WEIGHTING FRACTIONS

The HDDV travel weighting fractions are the individual model year proportions of the total HDDV VMT. To generate the HDDV travel weighting fractions, two distributions are required:

1. annual mileage accumulation rate distribution, and,
2. registration distribution.

These two distributions are given in Table 1.7.4. More detailed information is available in Chapter 1 on these distributions.

The travel weighting fractions in this document reflect a January 1 evaluation date. For the HDDVs, model year sales are assumed to begin on January 1 of that year. Further, it is assumed that the vehicles are sold and accumulate mileage according to a uniform distribution. The travel weighting fractions are given in Table 1.7.5.

Since it is assumed that there are no evaporative emissions from HDDVs, no trips per day or miles per day estimates are required for the calculation of HDDV emission factors.

7.D. EMISSION CORRECTION FACTORS

The HDDV basic exhaust emission levels are based on test results under the standard conditions defined in Section 4.A.1 of Chapter 4 and Section 7.A.1. However, the basic exhaust emission levels are affected by ambient and vehicle usage conditions which differ from the prescribed test procedure. The condition under which HDDV emissions are known to vary is the average speed. Emission correction factors are available to compensate for variations in these conditions.

Emissions from HDDVs emissions may be somewhat dependent on temperature, but that dependence is thought to be relatively insignificant. Also, EPA has no data to quantify the effect of temperature on HDDV emissions. Therefore, no temperature correction factor is used for HDDVs.

The use of air conditioning, carrying of an extra load, trailer towing, and humidity levels may affect HDDV emissions, but no information is available to estimate the effects.

7.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is a transient engine cycle with an estimated speed of about 20 mph. For those situations where the average speed of the vehicle deviates from this value, a speed correction factor is applied.

The coefficients for the speed correction factor equations are given in Table 1.7.6. The speed correction factors are only valid for speeds in the 2.5 through 55 mph range.

Chapter 8

MOTORCYCLES

8.A INTRODUCTION

A motorcycle (MC) is defined as any motor vehicle designed to travel with no more than three wheels in contact with the ground, and with a curb weight less than 1,500 pounds.

The MC fleet is composed of six engine size-type combinations: small, medium, and large engine sizes, with two-stroke and four-stroke engine types for each of the engine sizes. Since 1978, the motorcycle market has been dominated by four-stroke engines. The market trend in recent years has been toward increasing shares of the larger engine size motorcycles.

8.A.1 Test Procedure

With the exception of pre-1978 model years, the MC basic exhaust emission test procedure is similar to the LDGV test procedure. Therefore, the summary of the LDGV test procedure in Chapter 1 is also applicable to MCs. Given below is a list of pre-1978 model year motorcycle test procedure summary statistics that differ from the LDGV test procedure:

1. Average speed is 17.8 mph.
2. Average percent VMT in cold start operation is 18.3%.
3. Average percent VMT in hot start operation is 24.2%.
4. Average percent VMT in the stabilized operation is 57.5%.
5. Average trip length is 6.8 miles.
6. Test segments 1 (cold start) and 3 (hot start) each have an average trip length of 2.89 miles and average speed of 20.6 mph.
7. Test segment 2 (stabilized) has an average trip length of 3.91 miles and average speed of 16.2 mph.

8.A.2 General Emission Calculation Equations

The MC generalized equations are almost identical to the LDGV equations. The differences are:

1. three emission correction factors (air conditioning, extra load, and trailer towing) are not applicable to motorcycles, and
2. the effects of tampering are not included for motorcycles.

8.B EMISSIONS

This section discusses the MC emission estimates: basic exhaust emission rates, crankcase emissions, other evaporative HC emission components, January 1 emission levels, and idle emission rates. The emission standards are given in Section A.1.5 of Appendix A. The emissions reflect motorcycles which have received typical in-use maintenance. Further, the motorcycles are not involved in an I/M or anti-tampering program.

Due to lack of data, it is assumed that there are no running loss or refueling emissions from motorcycles.

Also, MCs are not subject to the types of tampering that EPA gathers information on in its tampering surveys, therefore tampering offsets are not added to MC emission factors.

With the exceptions noted above, the discussions of the different emissions in Chapter 1 are also valid for MCs.

8.B.1 Basic Exhaust Emission Rates

The basic nontampered exhaust emission rates for MCs are calculated from two variables:

1. zero mile emission levels, and,
2. emission deterioration rates for vehicles at all mileages.

The MC basic exhaust emission rates by model year group and pollutant are given in Table 1.8.1.

8.B.2 Crankcase and Evaporative HC Emission Levels

The MC crankcase, hot soak, and diurnal emissions at both 9.0 and 11.5 psi RVP fuels, from nontampered vehicles tested under FTP conditions, are summarized in Table 1.8.2.

8.B.3 January 1 Emission Levels

The emission levels for 20 model years on January 1 of the selected 24 calendar years are given in Tables 1.8.11A through 1.8.11C for HC, CO, and NOx, respectively. The HC emission levels reflect non-methane HC emissions, and include crankcase and two other evaporative HC emission components (hot soak and diurnal emissions).

8.B.4 Hot Stabilized Idle Emission Rates

The MC hot stabilized g/hr idle emission rates are given in Table 1.8.3.

8.C TRAVEL WEIGHTING FRACTIONS

The MC travel weighting fractions are the individual model year proportions of the total MC VMT. To generate the MC travel weighting fractions, two distributions are required:

1. annual mileage accumulation rate distribution, and,
2. registration distribution.

These two distributions are given in Table 1.8.4. More detailed information is available in Chapter 1 on these distributions.

The travel weighting fractions in this document reflect a January 1 evaluation date. For MCs, model year sales are assumed to begin on January 1 of that year. Further, it is assumed that the motorcycles are sold and accumulate mileage according to a uniform distribution. These assumptions permit the estimation of the January 1 fleet mileage accumulation rate distribution and the January 1 registration distribution from July 1 information. The travel weighting fractions are given in Table 1.8.5.

Average trips per day and miles per day estimates are used for MCs. These values are given in Table 1.8.2.

8.D EMISSION CORRECTION FACTORS

The MC basic exhaust emission levels are typically based on test results under the standard conditions defined in Chapter 1. However, the basic exhaust emission levels are affected by ambient and usage conditions which differ from the prescribed test procedure. The conditions under which emissions are known to vary are the average speed, ambient temperature, fraction of VMT in cold and hot start operating conditions, and humidity level. Emission correction factors are available to compensate for variations in these conditions.

The MC emission correction factors are based on the LDGV information. The discussions in Chapter 1 are valid for MCs.

8.D.1 Speed Correction Factor

The test procedure used for collecting the basic exhaust emissions is typically a driving cycle with an average speed of 17.8 mph. For those situations where the average speed of the MC differs from this value, a speed correction factor is applied. The MC speed correction factor equation and coefficients are given in Table 1.8.6.

8.D.2 Low and High Temperature Correction Factors

The established motorcycle emissions test procedure requires an ambient test temperature between 68° and 86°F. For those situations where the ambient temperature is not 75°F, an emission temperature correction factor is applied. Table 1.8.7A presents the low temperature correction factors and Table 1.8.7B presents the high temperature correction factors for MCs.

8.D.3 Temperature/Operating-Mode Emission Correction Factor

As in LDGVs, a single emission correction factor called OMTCF adjusts for temperature, and operating-mode conditions that differ from the basic test procedure. As described in Chapter 1, OMTCF depends on normalized bag fractions. The MC normalized bag fractions are given in Table 1.8.7C.

8.D.4 NO_x Humidity Correction Factor

The LDGV NO_x humidity correction factor equation is also used for MCs.

Appendix A

NEW VEHICLE EMISSION STANDARDS

This appendix presents the emission standards assumed in this document. At the time of the MOBILE4 release, these standards represent promulgated current and future standards. However, it is possible that some of the assumed standards are now different due to changes in regulations, waivers, etc.

In addition, EPA has promulgated emission standards for methanol-fueled vehicles and engines (see 54 FR 14426, April 11, 1989). These standards are not presented here, as they represent vehicles and engines that are not yet used in significant numbers and are not modeled in MOBILE4.

A.1 LOW- AND HIGH-ALTITUDE NON-CALIFORNIA HIGHWAY VEHICLE EMISSION STANDARDS

This section presents the emission standards for the eight low- and high-altitude non-California vehicle types. The standards are presented in five subsections. The light-duty vehicle and light-duty truck fleets are comprised of both diesel and gasoline-fueled vehicle types. The pre-1979 model year gasoline-fueled light-duty trucks (LDGT2s, 6001-8500 lbs gross vehicle weight) are heavy-duty vehicles, while 1979 and later model year LDGT2s are light-duty trucks. Finally, high-altitude standards are included in this section since there are relatively few emission standards specific to high-altitude vehicles.

All hydrocarbon emission standards presented in this section are for total hydrocarbon emissions.

A.1.1 Light-Duty Vehicles (LDVs)

The following standards apply only to gasoline-fueled LDVs through 1974. Standards for 1975 and later apply to both gasoline-fueled and diesel LDVs.¹

| <u>Year</u> | <u>Test Procedure</u> ² | <u>Hydro-carbons</u> | <u>Carbon Monoxide</u> | <u>Oxides of Nitrogen</u> | <u>Particulates</u> ³ | <u>Evaporative Hydrocarbons</u> ⁴ |
|----------------------------|------------------------------------|----------------------|---|--|--|--|
| Prior to controls | 7-mode | 850 ppm | 3.4 % | 1000 ppm | - | - |
| | 7-mode | 11 gpm | 80 gpm | 4 gpm | - | - |
| | CVS-75 | 8.8 gpm | 87.0 gpm | 3.6 gpm | - | - |
| 1968-69 | 7-mode | | | | | |
| | 50-100 CID | 410 ppm | 2.3 % | - | - | - |
| | 101-140 CID | 350 ppm | 2.0 % | - | - | - |
| | >140 CID | 275 ppm | 1.5 % | - | - | - |
| 1970 | 7-mode | 2.2 gpm | 23 gpm | - | - | - |
| 1971 | 7-mode | 2.2 gpm | 23 gpm | - | - | 6.0 g/test ⁵ |
| 1972 | CVS-72 | 3.4 gpm | 39 gpm | - | - | 2.0 g/test |
| 1973-74 | CVS-72 | 3.4 gpm | 39 gpm | 3.0 gpm | - | 2.0 g/test |
| 1975-76 | CVS-75 | 1.5 gpm | 15 gpm | 3.1 gpm | - | 2.0 g/test |
| 1977 ⁶ | CVS-75 | 1.5 gpm | 15 gpm | 2.0 gpm | - | 2.0 g/test |
| 1978-79 | CVS-75 | 1.5 gpm | 15 gpm | 2.0 gpm | - | 6.0 g/test |
| 1980 | CVS-75 | 0.41 gpm | 7.0 gpm | 2.0 gpm | - | 6.0 g/test |
| 1981 | CVS-75 | 0.41 gpm | 3.4 gpm ⁷ | 1.0 gpm ^{8, 9} | - | 2.0 g/test |
| 1982 ¹⁰ | CVS-75 | 0.41 gpm (0.57) | 3.4 gpm ⁷ (7.8) ¹¹ | 1.0 gpm ^{8, 9} (1.0) ^{8, 9} | 0.60 gpm (-) | 2.0 g/test (2.6) |
| 1983 ¹⁰ | CVS-75 | 0.41 gpm (0.57) | 3.4 gpm (7.8) | 1.0 gpm ⁸ (1.0) ⁸ | 0.60 gpm (0.60) | 2.0 g/test (2.6) |
| 1984-86 ¹² | CVS-75 | 0.41 gpm | 3.4 gpm | 1.0 gpm ⁸ | 0.60 gpm | 2.0 g/test |
| 1987 & later ¹² | CVS-75 | 0.41 gpm (0.41) | 3.4 gpm (3.4) | 1.0 gpm (1.0) | 0.20 gpm ¹³ (0.20) ¹³ | 2.0 g/test (2.0) |

LIGHT-DUTY VEHICLES - Notes

- 1 Standards do not apply to LDVs with engines less than 50 CID from 1968 through 1974.
- 2 Different test procedures have been used since the early years of emission control which vary in stringency. The appearance that the standards were relaxed from 1971 to 1972 is incorrect; the 1972 standards are actually more stringent because of the 1972 test procedure.
- 3 Applies only to diesel LDVs.
- 4 Evaporative emissions determined by carbon trap method through 1977, SHED procedure beginning in 1978. Applies only to gasoline-fueled LDVs. No crankcase emissions permitted from LDGVs beginning with 1968 model year.
- 5 Evaporative standard does not apply to off-road utility LDVs for 1971.
- 6 LDVs sold in specified high-altitude counties are required to meet these standards at high altitude.
- 7 Carbon monoxide standard is waived to 7.0 gpm for 1981-82 for certain LDVs.
- 8 Oxides of nitrogen standard is waived (to levels of 1.2 to 1.5 gpm) for certain innovative technology or diesel LDVs (applies to 1981-84 only).
- 9 Oxides of nitrogen standard for 1981-82 is 2.0 gpm for American Motors Corporation LDVs.
- 10 Standards in parentheses apply to LDVs sold in specified high-altitude counties.
- 11 LDVs eligible for a carbon monoxide waiver to 7.0 gpm at low altitude are eligible for a waiver to 11 gpm at high altitude.
- 12 The same numerical standards apply to LDVs sold in high-altitude areas. Exemptions from compliance at high-altitude are provided for qualifying low-performance vehicles.
- 13 Emissions averaging may be used to meet this standard, provided that emissions from LDVs produced for sale in California or in designated high-altitude areas may be averaged only within each of those areas. May also be averaged with LDDT1s to meet "composite particulate emission standard" as defined in Section 86.087-2, Code of Federal Regulations.

| | |
|--------|---|
| CID | - cubic inch displacement |
| CVS-72 | - constant volume sample cold start test |
| CVS-75 | - constant volume sample test including cold and hot starts |

| | CVS-75 (B) | 0.80 gpm (1.0) | 10 gpm (14) | *1.7 gpm ⁹ *(1.7) | 0.45 gpm (-) | 2.0 g/test (2.6) |
| 1991 & later ¹⁰ | CVS-75 (A) | 0.80 gpm (1.0) | 10 gpm (14) | 1.2 gpm ⁹ (1.2) | 0.26 gpm ⁹ (0.26) | 2.0 g/test (2.6) |
| | CVS-75 (B) | 0.80 gpm (1.0) | 10 gpm (14) | 1.7 gpm ⁹ (1.7) | 0.13 gpm ⁹ (0.13) | 2.0 g/test (2.6) |

* LDTs over 6,000 lbs GVW remain at 2.3 gpm NOx standard for 1988-89.

LIGHT-DUTY TRUCKS - Notes

- 1 Standards do not apply to LDTs with engines less than 50 CID from 1968 through 1974.
- 2 Different test procedures have been used since the early years of emission control which vary in stringency. The appearance that the standards were relaxed from 1971 to 1972 is incorrect; the 1972 standards are actually more stringent because of the 1972 test procedure.
- 3 Applies only to diesel LDTs.
- 4 Evaporative emissions determined by carbon trap method through 1977. SHED procedure beginning in 1978. Applies only to gasoline-fueled LDTs. No crankcase emissions permitted from LDGTs beginning with 1968 model year.
- 5 Evaporative standard does not apply to off-road utility LDTs for 1971.
- 6 LDTs sold in specified high-altitude counties required to meet standards at high altitude (1977 only).
- 7 Effective in 1979, the LDT classification was extended from 0-6,000 lbs GVWR to 0-8,500 lbs GVWR.
- 8 Standards in parentheses apply to LDTs sold in specified high-altitude counties. Manufacturers may choose to exempt up to 30 percent of their total LDT sales from demonstrating compliance with high-altitude standards (1982-84 only).
- 9 Emissions averaging may be used to meet this standard, provided that emissions from LDTs produced for sale in California or in designated high-altitude areas may be averaged only within each of those areas. NO_x emissions from diesel and gasoline-fueled LDT engine families may not be averaged together. NO_x emissions from LDTs over 6,000 lb GVW meeting 2.3 gpm NO_x standard for 1988-89 may not be averaged with LDTs meeting 1.2 or 1.7 gpm standards. Particulate emissions from LDDT2s may not be averaged together with particulate emissions from LDDVs and LDDT1s under the 0.13 gpm standard.
- 10 Standards under (A) apply to LDTs up to and including 3,750 lbs loaded vehicle weight (LVW); those under (B) apply to LDTs over 3,750 lbs LVW.

~~A-T~~

HEAVY-DUTY GASOLINE-POWERED ENGINES AND VEHICLES - Notes

- 1 Test procedure for 1970-83 standards is the 9-mode. For 1984, either the steady-state or transient test may be used. For 1985-86, either the EPA or MVMA transient test may be used. For 1987 and later, the MVMA transient test is used. Standards are engine standards except for evaporative emissions standards, which apply to vehicles. No crankcase emissions permitted from HDGVs beginning with 1968 model year.
- 2 The first set of numbers represents uncontrolled emissions as measured on the 9-mode test; the second, as measured on the EPA transient test; the third, as measured on the MVMA transient test.
- 3 Manufacturers may choose among the sets of standards listed.
- 4 Standards of 1.0 HC, 25 CO, and 9.5 NO_x may be used if NDIR HC measurement method is used.
- 5 Effective in 1979, the HDV classification was changed from >6,001 lbs GVWR to >8,501 lbs GVWR.
- 6 These standards are available as an option for low-volume manufacturers only.
- 7 At the manufacturers' option, the 1983 standards and test procedure may be used (option A), or the option B standards with the EPA transient test.
- 8 This standard was derived from the HC+NO_x standard when the transient test was adopted. It does not represent any significant level of control, although control of HC emissions has exerted an upward influence on NO_x emissions relative to baseline levels.
- 9 Standards of 1.9 HC, 37.1 CO, 10.6 NO_x are used with the MVMA transient test; the EPA transient test is used with standards of 2.5 HC, 40.0 CO, 10.7 NO_x. Evaporative standard is 3.0 g/test for HDVs 8,501-14,000 lbs GVWR, 4.0 g/test for those >14,000 lbs GVWR. (Evaporative standards do not apply to model year 1985 HDVs equipped with 1984 model year engines).
- 10 Standards under (A) apply to HDEs intended for use in HDVs <14,000 lbs GVWR; those under (B) apply to HDEs intended for use in HDVs >14,000 lbs GVWR. A manufacturer may certify up to 5 percent of HDEs intended for use in HDVs <14,000 lbs GVWR to the standards under (B) at its option. Test procedure is MVMA transient test.
- 11 Emissions averaging may be used to meet this standard; NO_x emissions from gasoline-fueled HDEs may not be averaged together with those from diesel HDEs. Also, averaging is restricted regionally; the two regions are California and the other 49 states.

| | |
|----------------|--|
| g/bhp-hr | - grams per brake horsepower-hour |
| GVWR | - gross vehicle weight rating |
| HDE/HDV | - heavy-duty engine/heavy-duty vehicle |

HEAVY-DUTY DIESEL-POWERED ENGINES AND VEHICLES - Notes

- 1 Test procedure for 1970-1983 standards is the 13-mode. Test procedure for 1985 and later is the transient test. No crankcase emissions permitted from naturally aspirated HDDVs beginning with 1984 model year.
- 2 Effective in 1979, the HDV classification was changed from $\geq 6,001$ lbs GVWR to $\geq 8,501$ lbs GVWR.
- 3 Manufacturers may choose from the two sets of standards listed.
- 4 At the manufacturers' option, either the 1983 standards and test procedure may be used (option A), or standards of 1.3 HC, 15.5 CO, and 10.7 NOx with the transient test (option B). Also, standards of 0.5 HC, 15.5 CO, and 9.0 NOx are optional standards for 1984 diesel HDEs tested on the 13-mode test.
- 5 Emissions averaging may be used to meet this standard, but these emissions may not be averaged with gasoline-fueled HDE NOx emissions. Averaging is restricted to within useful life subclasses (light, medium, and heavy; see 40 CFR 86.085-2). Also, averaging is restricted regionally; the two regions are California and the other 49 states.
- 6 Emissions averaging may be used to meet this standard. However, averaging is restricted to within useful life subclasses. Also, averaging is restricted regionally; the two regions are California and the other 49 states. Emissions from engines used in urban buses may not be included in the averaging program.
- 7 For urban bus engines only, the standard is 0.10 g/bhp-hr for 1991-93. Particulate averaging is not allowed with this standard, but NOx emissions from these engines may be used in NOx averaging.

| | |
|----------------|---|
| g/bhp-hr | - grams per brake horsepower-hour |
| ppm | - parts per million |
| 13-mode | - diesel engine dynamometer test with 13 steady-state test points |
| transient test | - engine dynamometer procedure with starts, stops, and speed/load changes |

~~A-10~~

A.1.5 Motorcycles

The following is a summary of motorcycle standards.¹

| <u>Year</u> | <u>Displacement</u> ² | <u>Hydrocarbons</u> | <u>Carbon Monoxide</u> |
|-------------------|----------------------------------|---------------------------------------|------------------------|
| Prior to controls | All (average) | 5.6 g/km | 21.5 g/km |
| 1978-79 | 50-169 | 5.0 g/km | 17 g/km |
| | 170-749 | 5.0 + 0.0155(D-170) g/km ³ | 17 g/km |
| | 750 & larger | 14 g/km | 17 g/km |
| 1980 & later | All (50 cc & larger) | 5.0 g/km | 12 g/km |

1 A motorcycle is any motor vehicle with a headlight, taillight, and stoplight, two or three wheels, and a curb mass of 680 kg (1500 lbs) or less. Motorcycles are exempt from these requirements if

- (1) displacement is less than 50 cc (3.1 in³), or,
- (2) with an 80 kg (176 lb) driver it cannot
 - (a) start from a dead stop using only the engine, or,
 - (b) exceed a speed of 40 km/hr (25 mi/hr) on a level paved surface.

2 Engine displacement shown in cubic centimeters.

3 Formula for motorcycle hydrocarbon standards, where D = engine displacement in cubic centimeters. For example, for a motorcycle with a 300 cc engine, the hydrocarbon standard is: $5.0 + [(300-170) \times .0155] = 7.0 \text{ g/km}$.

g/km - grams per kilometer
cc - cubic centimeters

Appendix B

CALCULATION OF THE VMT MIX

The proportion of the total vehicle-miles-traveled (VMT) driven by a given vehicle type depends on the following three parameters:

- (a) number of vehicles,
- (b) model year registration distribution, and,
- (c) mileage accumulation rate distribution.

Also, as light-duty diesel-powered vehicles and trucks become a larger proportion of their respective fleets, their VMT proportions will increase. As the diesel-powered vehicle type VMT fractions increase, the corresponding gasoline-powered vehicle type VMT fractions will decrease.

The MOBILE4 computer program calculates the VMT mix, unless the user inputs locality-specific information. The calculation procedure is based on the estimated number of vehicles and the average annual miles driven for each vehicle type. The product of these two variables estimates the total miles driven on January 1 of a calendar year for each vehicle type. By performing this calculation for each vehicle type and summing up the results, the total miles driven on January 1 for the entire highway mobile source fleet are obtained. Finally, by normalizing the individual vehicle type total miles, the VMT fractions are estimated.

The MOBILE4 computer program performs the calculations in subprogram TFCALX with the following equations:

$$\text{MILES(IV)} = \text{VCOUNT(IV)} * \text{GSFVCT(IV)} * \text{TFNORM(IV)}$$

$$\text{TOTVMT} = \text{SUMiv [MILES(IV)]}$$

$$\text{VMTMIX(IV)} = \text{MILES(IV)} / \text{TOTVMT}$$

where:

MILES(IV) = The estimated miles driven by vehicle type IV.

IV = The vehicle type index (1 = LDGV, 2 = LDGT1, 3 = LDGT2, 4 = HDGV, 5 = LDDV, 6 = LDDT, 7 = HDDV, 8 = MC).

VCOUNT(IV) = The estimated vehicle count for vehicle type IV based on registrations. To use the dieselization rates, MOBILE4 assumes that VCOUNT(1) = VCOUNT(5) and VCOUNT(2) = VCOUNT(6). This means that the LDGVs and

88

B-T

LDDVs combined constitute the light-duty vehicle fleet. Similarly, LDGT1s, LDGT2s, and LDDTs combined constitute the light-duty truck fleet. Both the light-duty vehicle and truck fleets are adjusted by diesel sales fractions to separate diesel from gasoline-powered vehicles/trucks.

GSFVCT(IV) = Sales fractions of each total (both gasoline- and diesel-powered) vehicle counts that are either gasoline- or diesel-powered. For example, GSFVCT (1) = DAF(1) / [DAF(1) + DAF(5)], where DAF is the fleet sum of the product of the registration distribution and the diesel sales fractions by model year in a given calendar year. The DAF values change with calendar year. Examples of how the DAF values are estimated are shown in the tables with numbers ending in .5 in Appendix H. Also, the diesel sales fractions by model year are given in Tables x.5.4B for the LDVs and in Tables x.6.4B for the LDTs.

TFNORM(IV) = The registration-weighted average of annual miles driven by each vehicle of vehicle type IV. The derivation of these values is illustrated in each of the tables with numbers ending in .5 in Appendix H (denoted as TFNORM at the bottom of the C*D column).

TOTVMT = The total miles traveled by the entire highway mobile source fleet.

SUMiv = The summation over the eight vehicle types.

VMTMIX(IV) = The estimated VMT fraction for vehicle type IV.

An example of the VMT mix calculation follows. This example is based on the travel weighting factor calculation tables (Tables x.x.5 in Appendix H) and registration counts for the January 1, 1988 VMT mix estimates:

Step 1: Estimate GSFVCT values for each of the vehicle types.

| <u>IV</u> | <u>DAF</u> | <u>Adjustment</u> | <u>GSFVCT</u> |
|-----------|------------|-----------------------|---------------|
| 1 | 0.944 | 0.944/(0.944 + 0.014) | 0.985 |
| 2 | 0.929 | 0.929/(0.929 + 0.024) | 0.975 |
| 3 | 0.929 | 0.929/0.929 | 1.0 |
| 4 | 0.935 | 0.935/0.935 | 1.0 |
| 5 | 0.014 | 0.014/(0.944 + 0.014) | 0.015 |
| 6 | 0.024 | 0.024/(0.929 + 0.024) | 0.025 |
| 7 | 0.918 | 0.918/0.918 | 1.0 |
| 8 | 0.904 | 0.904/0.904 | 1.0 |

~~B-3~~

Step 2: Calculate VMTMIX according to the equations given above.

| <u>IV</u> | <u>VCOUNT</u> | <u>GSFVCT</u> | <u>TFNORM</u> | <u>MILES</u> | <u>VMTMIX</u> |
|-----------|---------------|---------------|---------------|------------------------|---------------|
| 1 | 117,268,000 | 0.985 | 9,253.6 | 10.69×10^{11} | 0.708 |
| 2 | 18,634,000 | 0.975 | 10,604.2 | 1.93×10^{11} | 0.128 |
| 3 | 11,518,000 | 1.0 | 11,243.4 | 1.26×10^{11} | 0.086 |
| 4 | 1,854,000 | 1.0 | 12,397.5 | 0.23×10^{11} | 0.015 |
| 5 | 117,268,000 | 0.015 | 11,382.8 | 0.20×10^{11} | 0.013 |
| 6 | 18,634,000 | 0.025 | 11,566.7 | 0.09×10^{11} | 0.004 |
| 7 | 1,301,000 | 1.0 | 41,840.1 | 0.54×10^{11} | 0.036 |
| 8 | 4,179,000 | 1.0 | 3,657.4 | 0.15×10^{11} | 0.010 |
| | | | Total | 15.09×10^{11} | |

90

Appendix C

CALCULATION PROCEDURE TO COMBINE THE EMISSION RESULTS OF THE TWO LIGHT-DUTY GASOLINE-POWERED TRUCK CLASSES

Frequently air quality analyses require the use of one light-duty gasoline-powered truck vehicle type, as opposed to two. However, emission factors are presented for two truck types: LDGT1s and LDGT2s. As a result, a procedure based on VMT has been developed to combine the two truck types. This appendix describes this procedure.

The generalized formula is as follows:

$$\frac{VMT(LDGT1) \times EF(LDGT1) + VMT(LDGT2) \times EF(LDGT2)}{VMT(LDGT1) + VMT(LDGT2)}$$

To illustrate this, an example based on January 1, 1988 emission factor results is used. On January 1, 1988, the LDGT1 and LDGT2 calculated CO emission factors (based on standard FTP conditions and in-use 11.5 psi RVP fuels) are 39.37 and 41.27 grams/mile, respectively. Further, from Appendix B, the LDGT1 and LDGT2 proportions of the total fleet VMT are 12.8 percent and 8.6 percent, respectively. Finally, also from Appendix B, the entire fleet travels 15.09×10^{11} miles.

The combined truck types travel the following miles on January 1, 1988:

$$(15.09 \times 10^{11} \text{ miles}) * 0.128 + (15.09 \times 10^{11} \text{ miles}) * 0.086 \\ = 1.93 \times 10^{11} \text{ miles} + 1.30 \times 10^{11} \text{ miles}$$

The total grams emitted by the combined truck types are:

$$(1.93 \times 10^{11} \text{ miles}) * 39.37 \text{ g/mi} \\ + (1.30 \times 10^{11} \text{ miles}) * 41.27 \text{ g/mi}$$

As a result, the calculated CO gram/mile emission factor estimate for the combined truck type is, in total grams/total miles:

$$[(15.09 \times 10^{11} \text{ miles}) * 0.128 * 39.37 \text{ g/mi} \\ + (15.09 \times 10^{11} \text{ miles}) * 0.086 * 41.27 \text{ g/mi}] \\ / [(15.09 \times 10^{11} \text{ miles}) * 0.128 + (15.09 \times 10^{11} \text{ miles}) * 0.086]$$

or,

$$\frac{0.128 * 39.37 \text{ g/mi} + 0.086 * 41.27 \text{ g/mi}}{0.128 + 0.086} = 40.14 \text{ g/mi.}$$

Appendix D

METHODOLOGY FOR CALCULATING JANUARY 1 TRAVEL WEIGHTING INFORMATION AND FLEET AVERAGE MILEAGE ACCUMULATION

This appendix describes the derivation of January 1 registration distributions, the annual rate of mileage accrual for the fleet, and the fleet average mileage accumulation distributions. The January 1 registration and annual rate of mileage accrual distributions are used in the calculation of travel weighting fractions. The fleet average mileage accumulation distributions are used to estimate the January 1 emission levels by model year.

D.1 JANUARY 1 TRAVEL WEIGHTING INFORMATION

The travel weighting fractions for a given vehicle type are the individual model year proportions of the total VMT for the vehicle type. To generate the travel weighting fractions, three distributions are required:

- (a) annual mileage accrual rate per vehicle by age distribution,
- (b) registration distribution, and,
- (c) diesel sales fraction distribution.

D.1.1 January 1 Registration Distribution Transformations

The first step of the January 1 travel fraction calculation procedure is to estimate the January 1 model year registration distribution for each vehicle type. The model year registration distribution, frequently referred to as the registration mix, begins with all model years combined for a given vehicle type and apportions them into their appropriate model year index (except for model year index 20, which represents all model years that were built 20 or more model years ago). At this phase of the registration mix development, the LDV and LDT model year registration distributions are composed of both the gasoline- and diesel-powered vehicle types.

For the MOBILE4 computer program, the initial model year registration distributions are assumed to be based on July 1 data. This July 1 information is then transformed into January 1 model year registration distributions. For vehicle types where sales begin on October 1 (such as light-duty vehicles and trucks), it is assumed that the original July 1 model year registration distribution accounts for approximately 75 percent of the current model year fleet. Using the assumption of uniform sales throughout the year, approximately 25 percent of the model year fleet would have been sold by January 1 (or one-third of the July 1 registration).

92

D+

~~D-2~~

The older model year registration figures are six months older on July 1 than they are on January 1. However, no direct adjustment are made to these older model year registration values. Although the difference between January 1 and July 1 for the older model vehicles is primarily due to scrappage, the older model year registration values are to be adjusted later.

Denoting the July 1 registration fractions as $R(1)$, $R(2)$, $R(3)$, . . . , $R(20+)$, the January 1 adjustment equations can be generalized as follows:

FIRST MODEL YEAR INDEX: $1/3 * R(1)$
SECOND AND LATER MODEL YEAR INDEX: $R(i)$, $i=2, 3, \dots, 20+$

The second step of adjustment for the January 1 model year registration distributions is to account for the gasoline/diesel sales fractions: the separation of the model year sales into diesel- and gasoline-powered vehicle types. (The diesel sales fractions by model year are given in Tables x.5.4B for LDVs and x.6.4B for LDTs in Appendix H.) As a result, the January 1 model year registration distributions are adjusted according to the following formulae:

FIRST MODEL YEAR INDEX: $1/3 * R(1) * F(my)$
SECOND AND LATER MODEL YEAR INDEX: $R(i) * F(my-i+1)$

where $F(my)$ is the model year sales fractions which are gasoline-powered if calculating the LDGV or LDGT registration distributions, or the model year sales fractions which are diesel-powered if calculating the LDDV or LDDT registration distributions.

The last step of adjustment is to normalize the January 1 model year registration distribution so that the fractions from each model year index sum up to unity. To accomplish this adjustment, the following procedure is used:

$$DAF = \sum_i [P(i) * R(i) * F(my-i+1)]$$

where:

$P(1) = 1/3$
 $P(i) = 1, \text{ for } i = 2, 3, \dots, 20+$
 $R(i) = \text{July 1 registration values, } i = 1, 2, 3, \dots, 20+$
 $F(my-i+1) = \text{sales fractions (either gasoline or diesel) for model year my-i+1}$
 $\sum_i = \text{summation over the 20 model years.}$

Then for each January 1 registration, the value of $P(i)*R(i)*F(my-i+1)$ is divided by DAF to estimate the January 1 registration mix.

For vehicles whose sales begins on January 1 (such as heavy-duty vehicles and motorcycles), there are two changes to the above normalization procedure: P(1) is set to zero, and every F(my-i+1) term is set to 1.0.

D.1.2 January 1 Annual Rate of Mileage Accrual for the Fleet

The last aspect of calculating the travel weighting fractions is to determine the January 1 annual rate of mileage accrual. The following example illustrates the methodology used for calculating the average mileage accumulation rate for the 1988 model year (MY) LDGVs on January 1 of 1988, 1989, 1990, and later years.

First, the average annual mileage accumulation rate of the MY 1988 LDGVs on January 1, 1988, is calculated (i.e., the calendar year when the vehicle model year index is one). It is assumed that mileage accrual is uniform throughout the year and that 1988 LDGV model year sales begin on October 1, 1987.

Using these assumptions, it is obvious that by January 1, 1988, all 1988 MY vehicles are less than one year old and accumulate mileage at the first year rate of 13,118 miles. (The annual rates of mileage accrual of LDGVs are presented in Table 1.1.4A of Appendix H.) By January 1, 1989, those vehicles that were sold by January 1, 1988 have been on the road for an additional year and accumulate mileage at the second year annual rate of 12,408 miles.

In addition to the MY 1988 vehicles sold before January 1, 1988, there are also those sold after January 1 and before October 1, 1988. Again by assuming uniform sales, approximately 75 percent of the MY 1988 vehicles are sold after January 1, 1988. Further, on January 1, 1989 these vehicles are still in their first year of mileage accumulation and are accumulating mileage at an annual rate of 13,118 miles.

Since the first group represents three months of sales and the second group represents nine months of sales, the average annual mileage accrual rate of MY 1988 vehicles on January 1, 1989 can be expressed as follows:

$$(0.25 * 12,408 \text{ miles}) + (0.75 * 13,118 \text{ miles})$$

By extension, the formula for the average mileage accumulation rate of the MY 1988 vehicles on January 1, 1990 is as follows:

$$(0.25 * 11,737 \text{ miles}) + (0.75 * 12,408 \text{ miles})$$

Denoting the average annual rate of mileage accrual during the first, second, and third year as $M(1)$, $M(2)$, and $M(3)$, respectively, the generalized average annual mileage accumulation rate equations on January 1 are as follows:

FIRST MODEL YEAR INDEX: $M(1)$
SECOND MODEL YEAR INDEX: $0.25 * M(2) + 0.75 * M(1)$
THIRD MODEL YEAR INDEX: $0.25 * M(3) + 0.75 * M(2)$
 I^{th} MODEL YEAR INDEX: $0.25 * M(i) + 0.75 * M(i-1)$

For the vehicle types whose sales begin on January 1 (such as heavy-duty vehicles and motorcycles), the generalized formulae are as follows:

FIRST MODEL YEAR INDEX: 0
 I^{th} MODEL YEAR INDEX: $M(i-1)$

D.2 JANUARY 1 FLEET AVERAGE MILEAGE ACCUMULATION

To estimate the emission levels on January 1 for each model year (as shown in Tables x.(IV).11A through x.(IV).11C of Appendix H for each vehicle type), the annual mileage accrual rate per vehicle by age is used to derive the fleet average mileage accumulation distribution.

The following example explains the methodology used for calculating the average January 1 fleet cumulative mileages for the 1988 model year (MY) LDGVs on January 1 of 1988, 1989, 1990, and later years.

First, the average fleet cumulative mileage of the MY 1988 vehicles on January 1, 1988 (i.e., the calendar year when the vehicle model year index is defined as "1") is calculated. As described in the previous section, MOBILE4 assumes that both the vehicle sales and the vehicle mileage accrual are uniformly distributed throughout the year, and for LDGVs the MY 1988 sales began on October 1, 1987. Then, by January 1, 1988 (25 percent of the way through the sales year), approximately 25 percent of the 1988 model year vehicles would have been sold. These vehicles range in age from 0 to 3 months. Assuming uniform sales, their average age is 1.5 months.

The average mileage accrual for these MY 1988 vehicles which were sold by January 1, 1988 is $1.5/12.0$ (or 0.125) multiplied by the annual rate of mileage accumulation of 13,118 miles for the first year. (The annual mileage accrual rates for LDGVs are presented in Tables x.1.4A and x.1.5 of Appendix H.) By January 1, 1989, vehicles sold before January 1, 1988 have been on the road for an additional year. Therefore, they have accumulated mileage for $1.0 + (1.5/12.0)$ years (or 1.125 years). Referring to Table 1.1.4A for the rates of annual mileage accrual, the average cumulative mileage of these vehicles are calculated as the sum of the first year's mileage of 13,118 miles plus 0.125 multiplied by the second year mileage rate of 12,408 miles.

In addition to the 1988 MY vehicles sold before January 1, 1988, there are also those sold between January 1, 1988 and September 30, 1988. Again by the uniform sales assumption, by January 1, 1989 these vehicles range in age from 3 to 12 months, with an average age of 7.5 months. Since these vehicles are still in their first year of use on January 1, 1989, their average mileage accumulation is $7.5/12.0$ (or 0.625) multiplied by 13,118 miles.

The average cumulative mileage of all MY 1988 LDGVs on January 1, 1989 is the sales weighted average of the cumulative mileages for these two groups of vehicles (those sold before January 1 and those sold after January 1). Since the first group represents three months of sales and the second group represents nine months of sales, the weighted average cumulative mileage of MY 1988 vehicles on January 1, 1989 can be expressed as follows:

$$0.25 * (13118 \text{ miles} + 0.125 * 12408 \text{ miles}) \\ + 0.75 * (0.625 * 13118 \text{ miles})$$

By extension, the formulae for the cumulative mileage of 1988 MY vehicles on January 1, 1990 is given by:

$$0.25 * (13118 \text{ miles} + 12408 \text{ miles} + 0.125 * 11737 \text{ miles}) \\ + 0.75 * (13118 \text{ miles} + 0.625 * 12408 \text{ miles})$$

Denoting the average rate of mileage accumulation during the first, second, and third years as $M(1)$, $M(2)$, and $M(3)$, we can generalize the equations for cumulative mileage on January 1 as follows:

$$\begin{aligned} \text{FIRST YEAR: } & 0.125 * M(1) \\ \text{SECOND YEAR: } & 0.25 * [M(1) + 0.125 * M(2)] + 0.75 * [0.625 * M(1)] \\ \text{THIRD YEAR: } & M(1) + 0.25 * [M(2) + 0.125 * M(3)] \\ & + 0.75 * [0.625 * M(2)] \\ \text{Ith YEAR: } & M(1) + M(2) + \dots + M(i-2) + 0.25 * [M(i-1) + \\ & 0.125 * M(i)] + 0.75 * [0.625 * M(i-1)] \end{aligned}$$

For vehicles whose sales year begins on January 1 (e.g., heavy-duty vehicles and motorcycles), the formulae are simplified as follows:

$$\begin{aligned} \text{FIRST YEAR: } & 0 \\ \text{SECOND YEAR: } & 0.5 * M(1) \\ \text{THIRD YEAR: } & M(1) + M(2) + \dots + M(i-2) + 0.5 * M(i-1) \end{aligned}$$

Appendix E

METHOD FOR DETERMINING EMISSIONS DUE TO OR INCLUDING TAMPERING AND MISFUELING

E.1 BACKGROUND

Since 1978, EPA has been conducting surveys of in-use vehicles (passenger cars and trucks) nationwide, collecting data regarding emission component disablements and misfueling. Three of the latest available surveys, completed in 1984, 1985, and 1986, were chosen as the data base for MOBILE4 tampering and misfueling rates.

Tampering and misfueling rates are determined for four vehicle types (LDGVs, LDGT1s, LDGT2, and HDGVs) only. Due to lack of information on both rates and effects, no tampering and misfueling rates are assumed for other vehicle types. Separate tampering rates are used for non-I/M areas and areas with I/M programs, for nine different categories: air pump disablement, catalyst removal, EGR system disabled, filler neck damaged, fuel tank misfueled, total misfueled, PCV system disabled, canister disconnect, and both canister and fuel cap removal. Total misfueled is the sum of the filler neck damaged and fuel tank misfueled categories. For the light-duty vehicles and trucks, two separate groups are considered: pre-1981 model years, and 1981 and later model years.

As in MOBILE3, linear regression equations on mileage were fit to the three year survey data. In MOBILE4, each equation is defined by a zero mile rate, an increase in the rate for every 10,000 miles of fleet average mileage for the first 50,000 miles, and (depending on vehicle type and tampering category) either the same or a different increase in the rate for every 10,000 miles of fleet average mileage after 50,000 miles.

The regression coefficients are given in Tables z.(IV).9A in Appendix H. In these tables, some coefficients at the zero-mile level are negative. However, if a tampering or misfueling rate for a particular model year is calculated to be less than zero in the evaluation year, that rate is set to zero.

Also in Tables z.(IV).9A, the overlap among tampering types is ignored. One vehicle could contribute to several of the regression equations. The overall tampering rate at a given mileage is, therefore, less than the sum of these equations. However, when estimating the excess emissions due to tampering, it is necessary to explicitly account for vehicles with more than one form of tampering, since tampering effects on emissions are not always additive. The following sections describe the methodology with an illustrated example.

E-1

97

The method described below assumes that the user is interested in a situation in which vehicles are driven under standard conditions of temperature, speed, etc. All of the emission impacts shown in this document assume such a situation as well. It is possible to analyze other situations if correction factors for non-standard conditions are applied at an appropriate step in the calculation. MOBILE4 does this automatically.

E.2 Discussion of Methodology

The approach used begins with a single model year vehicle. The calculation is performed for each of the last 19 model years, resulting in a total emissions impact for each from all forms of tampering combined. These 19 model-year-specific impacts are then added using age-based vehicle-miles-traveled (VMT) fractions as weighting factors to arrive at the impact on the composite emissions of, for example, the LDGVs of all ages.

The discussion below is for low-altitude LDGVs. The same procedure is used for LDGT1s, LDGT2s, or HDGVs by substituting the appropriate tampering rates, emission impacts, etc. The calculation consists of the following steps for each model year.

Step 1:

Separate the model year into subgroups with distinct combinations of equipment, such that all vehicles in a subgroup are susceptible to the same types of tampering. Specifically, vehicles with catalyst and air pump must be separated from vehicles with air pump only, and from vehicles with catalyst only, since simultaneous air pump and catalyst tampering is possible for one subgroup but not the others. The sales fractions for each of these subgroups must also be known. (These fractions are given in Table 1.1.10C of Appendix H.)

In a single model year, vehicles either have or do not have PCV and evaporative controls. The fuel cap is considered as a part of the evaporative control system. The impacts of PCV and evaporative control system tampering are independent from the impacts of other types of tampering, such as misfueling, catalyst removal, and air pump disablement. For these reasons, there is no need to define subgroups based on PCV and evaporative equipment.

Step 2:

Identify all the unique combinations of tampering that could occur in each subgroup. These are as follows:

| <u>Air Pump/Catalyst</u> | <u>Catalyst Only</u> | <u>Air Pump Only</u> |
|--|----------------------|----------------------|
| 1. Air Pump/Catalyst | | |
| 2. Air Pump/Filler Neck Damaged | | |
| 3. Air Pump/Fuel Tank Misfueled | | |
| 4. Air Pump/Catalyst/Filler Neck Damaged | | |
| 5. Air Pump/Catalyst/Fuel Tank Misfueled | | |
| 6. Catalyst/Filler Neck Damaged | X | |
| 7. Catalyst/Fuel Tank Misfueled | X | |
| 8. Air Pump Only | | X |
| 9. Catalyst Only | X | |
| 10. Filler Neck Damaged Only | X | |
| 11. Fuel Tank Misfueled Only | X | |

In the above list, "Filler Neck Damaged" designates habitual misfueling accompanied by tampering of the fuel inlet restrictor, "Fuel Tank Misfueled" designates habitual misfueling accomplished by other means, such as a small pump nozzle or a funnel.

Step 3:

Find the percentage of vehicles with each of the above unique combinations of tampering on the evaluation date, assuming no special program to reduce tampering and misfueling. These rates are described in Tables 1.1.9A, and are functions of the model year vehicle mileage on the evaluation date (January 1). (The mileage accumulation rate is given in Table 1.1.4A of Appendix H). Given an odometer value, the coefficients from Table 1.1.9A can be used to calculate the overall rates of tampering for air pump disablement (AIR), catalyst removal (CAT), misfueling via damaged filler neck (INLET), and fuel tank misfueled (OTHER).

These overall tampering rates are the sum of the rates for two or more of the above unique combinations of tampering. To calculate the individual rate for each unique combination, additional assumptions are necessary. EPA has assumed that the rate for a given overlap combination is always proportional to the overall rate of one or the other of the forms of tampering that make up the overlap combination. For example, the rate of simultaneous air pump and catalyst tampering affecting HC/CO emissions for 1981 and later model year LDGVs is 6.08 percent of the overall air pump tampering rate, regardless of any local variation in overall air pump tampering rate or overall catalyst tampering rate. This 6.08 percentage value, called the category size factor, was determined from the tampering survey data.

The category size factors used in MOBILE4 are defined by the pollutant affected (either HC/CO or NOx), and by the model year group (pre-1981 vs. 1981 and later model years):

| <u>Air Pump/Catalyst</u> | <u>HC/CO Emissions</u> | | <u>NOx Emissions</u> | |
|--|------------------------|--------------|----------------------|--------------|
| | <u>Pre-1981</u> | <u>1981+</u> | <u>Pre-1981</u> | <u>1981+</u> |
| 1. Air Pump/Catalyst | 0.2025 | 0.0608 | 0.1349 | 0.0786 |
| 2. Air Pump/Filler Neck Damaged | 0.1942 | 0.1466 | 0.0353 | 0.0137 |
| 3. Air Pump/Fuel Tank Misfueled | 0.0423 | 0.0363 | 0.0161 | 0.0149 |
| 4. Air Pump/Catalyst/Filler Neck Damaged | 0.3454 | 0.2516 | 0.1392 | 0.0778 |
| 5. Air Pump/Catalyst/Fuel Tank Misfueled | 0.0270 | 0.0283 | 0.0263 | 0.0 |
| 6. Catalyst/Filler Neck Damaged | 0.2371 | 0.3750 | 0.1899 | 0.2780 |
| 7. Catalyst/Fuel Tank Misfueled | 0.1176 | 0.0802 | 0.0526 | 0.0750 |

Necessary adjustments are made to prevent any logical contradiction. In the example given below, the rates of simultaneous filler neck damaged from vehicles with air pump only, from vehicles with catalyst only, and from vehicles equipped with catalyst and air pump are assumed to be equal to or less than the overall rate of filler neck damaged. Similar assumptions are made for other overlap combinations. The resultant tampering rates for each unique combination are used for calculating both the excess exhaust and the excess idle emissions. An example of the assumptions is as follows:

| <u>Air Pump/Catalyst</u> | <u>Rate</u> |
|--|-------------------|
| 1. Air Pump/Catalyst | 0.0608 x AIR |
| 2. Air Pump/Filler Neck Damaged | 0.1466 x AIR |
| 3. Air Pump/Fuel Tank Misfueled | 0.0363 x AIR |
| 4. Air Pump/Catalyst/Filler Neck Damaged | 0.2516 x CAT |
| 5. Air Pump/Catalyst/Fuel Tank Misfueled | 0.0283 x CAT |
| 6. Catalyst/Filler Neck Damaged | 0.3750 x CAT |
| 7. Catalyst/Fuel Tank Misfueled | 0.0802 x CAT |
| 8. Air Pump Only | AIR - (1,2,3,4,5) |
| 9. Catalyst Only | CAT - (1,4,5,6,7) |
| 10. Filler Neck Damaged Only | INLET - (2,4,6) |
| 11. Fuel Tank Misfueled Only | OTHER - (3,5,7) |

PCV tampering rates come directly from the coefficients in Table 1.1.9A. Two sets of tampering rates are given for evaporative control system tampering: both canister and fuel cap disconnect, and canister disconnect. Therefore, the rate of fuel cap removal alone is to be calculated from the difference between the two rates.

Step 4:

Assign each unique combination of tampering an emissions impact (excess emissions or uncontrolled emissions) per vehicle. The impacts are taken from Table 1.1.9B for the exhaust and idle excess emissions, Table 1.1.9C for the uncontrolled evaporative crankcase, hot soak and diurnal emissions, and Table 1.1.9D for the uncontrolled evaporative running loss emissions. The following assumptions applied to cases of simultaneous tampering:

- 1) The impact of simultaneous catalyst removal and of misfueling and/or air pump tampering is the same as stated in Table 1.1.9B for catalyst removal alone.
- 2.) The impact of simultaneous misfueling and air pump tampering is the same as stated in Table 1.1.9B for misfueling alone.

Step 5:

Multiply the tampering rate by the emissions impact for each unique combination, then add the result for all combinations, taking into account the sales split between the air pump only subgroup, the catalyst only subgroup, and the air pump- and catalyst-equipped subgroup. The sum is the excess exhaust or idle emissions due to the tampering and misfueling.

Composite excess exhaust or idle emissions can be calculated by weighting each model year by its age-based VMT fraction (also known as the travel fraction).

Excess crankcase emissions due to PCV tampering are calculated from the PCV tampering rate, emissions impact, and fractions equipped with PCV.

Step 6:

Except for crankcase evaporative emissions, all other evaporative emissions (hot soak, diurnal, and running loss) including tampering are calculated from the following six components: nontampered emission rate, fraction of nontampered fleet, uncontrolled emissions due to canister disconnect, fractions of the fleet with canister disconnect, uncontrolled emissions due to fuel cap removal, and fractions of the fleet with fuel cap removal. Excess emissions are, therefore, calculated internally from uncontrolled and controlled evaporative emission levels.

E.3 Example Calculation

This example calculates the excess emissions due to tampering and misfueling for the 1982 model year LDGVs evaluated on January 1, 1988. It is assumed that the vehicles are located in a non-I/M area, with the national average tampering and misfueling rates described in Table 1.1.9A. The average 1982 model year vehicle is estimated to have accumulated 66,303 miles by January 1, 1988 (from Table 1.1.4A under model year index 7).

Table E-1

Example Calculation of Tampering and Misfueling Rates*

| System | Zero-Mile Level(A) | Increase/10K miles(B) (< 50K mi) | Increase/10K miles(C) (> 50K mi) | Rate** at 66,303 mi = X |
|----------------------|--------------------|-------------------------------------|-------------------------------------|----------------------------|
| Air Pump Disablement | -0.0157 | 0.00961 | 0.03819 | 0.0946 |
| Catalyst Removal | -0.0071 | 0.00574 | 0.01546 | 0.0468 |
| Filler Neck Damaged | -0.0068 | 0.00496 | 0.00496 | 0.0261 |
| Fuel Tank Misfueled | 0.0140 | 0.00101 | 0.00101 | 0.0207 |
| PCV System Disabled | -0.0059 | 0.00315 | 0.00315 | 0.0150 |
| Canister Disconnect | -0.0206 | 0.01154 | 0.01154 | 0.0559 |
| Both Canister & Cap | -0.0186 | 0.01301 | 0.01301 | 0.0677 |

* Non-I/M area LDGVs.

**Rate = A + B*5.0 + C*(X/10K - 5.0).

The overall rates are then used to estimate the size of the eleven overlap categories. These categories do not include PCV and evaporative control system tampering, which are to be addressed later in this section. (As mentioned in Section E.2, Step 1, the evaporative control system tampering also includes the fuel cap removal.) For HC and CO excess exhaust emissions, there are three technology types of interest: 1) air pump only, 2) catalyst only, and, 3) catalyst with air pump.

The category sizes for air pump only and catalyst only are calculated directly from the coefficients in Table 1.1.9A, as shown from Table E-1 to be 0.0946 and 0.0468, respectively. The category sizes for catalyst with air pump are shown below, using the equations and category size factors described in Section E.2, Step 3.

| <u>Category Description*</u> | <u>Equation** from Section E.2, Step 3</u> | <u>Category Size at Evaluation</u> |
|------------------------------|--|------------------------------------|
| 1. AIR/CAT | 0.0608 x AIR | 0.00575 |
| 2. AIR/INLET | 0.1466 x AIR | 0.01387 |
| 3. AIR/OTHER | 0.0363 x AIR | 0.00347 |
| 4. AIR/CAT/INLET | 0.2516 x CAT | 0.01178 |
| 5. AIR/CAT/OTHER | 0.0283 x CAT | 0.00132 |
| 6. CAT/INLET | 0.3750 x CAT | 0.01755 |
| 7. CAT/OTHER | 0.0802 x CAT | 0.00375 |
| 8. AIR | AIR - (1,2,3,4,5) | 0.05841 |
| 9. CAT | CAT - (1,4,5,6,7) | 0.00665 |
| 10. INLET | INLET - (2,4,6) | -.01710 |
| 11. OTHER | OTHER - (3,5,7) | 0.01216 |

Note that the category size of INLET from the above table is less than zero (-0.01710), as the overall INLET from Table E-1 is 0.0261, which is less than the sum of 0.0432 from the three subgroups (2, 4, and 6). An adjustment is made so that the sum of the three subgroups be equal to the overall rate of 0.0261, as shown below:

| <u>Category Description*</u> | <u>Category Size at Evaluation</u> | <u>Adjustment</u> | <u>Adjusted Category Size</u> |
|------------------------------|------------------------------------|--------------------|-------------------------------|
| 2. AIR/INLET | 0.01387 | .01387/.0432*.0261 | 0.00833 |
| 4. AIR/CAT/INLET | 0.01178 | .01178/.0432*.0261 | 0.00712 |
| 6. CAT/INLET | 0.01755 | .01755/.0432*.0261 | 0.01060 |
| Total: | | 0.04320 | |

* AIR = Air pump disablement, CAT = Catalyst removal, INLET = Misfueling by enlarging fuel filler neck, and OTHER = fuel tank misfueled.

** Rates for AIR, CAT, INLET, and OTHER from Table E-1.

With the adjustments, the revised overlap categories are shown in Table E-2.

Table E-2
Revised Overlap Categories

| <u>Category Description*</u> | <u>Equation** from Section E.2, Step 3</u> | <u>Category Size at Evaluation</u> |
|------------------------------|--|------------------------------------|
| 1. AIR/CAT | 0.0608 x AIR | 0.00575 |
| 2. AIR/INLET | 0.1466 x AIR | 0.00833 |
| 3. AIR/OTHER | 0.0363 x AIR | 0.00347 |
| 4. AIR/CAT/INLET | 0.2516 x CAT | 0.00712 |
| 5. AIR/CAT/OTHER | 0.0283 x CAT | 0.00132 |
| 6. CAT/INLET | 0.3750 x CAT | 0.01060 |
| 7. CAT/OTHER | 0.0802 x CAT | 0.00375 |
| 8. AIR | AIR - (1,2,3,4,5) | 0.06861 |
| 9. CAT | CAT - (1,4,5,6,7) | 0.00665 |
| 10. INLET | INLET - (2,4,6) | 0.0 |
| 11. OTHER | OTHER - (3,5,7) | 0.01216 |

* AIR = Air pump disablement, CAT = Catalyst removal, INLET = Misfueling by enlarging fuel filler neck, and OTHER = fuel tank misfueled.

** Rates for AIR, CAT, INLET, and OTHER from Table E-1.

Next, the emission impacts of each of the categories must be determined. Since all of the 1982 model year vehicles are equipped with either an oxidation catalyst or a 3-way oxidation catalyst, the HC/CO emission impacts of air pump disablement, catalyst removal and misfueling can be taken directly from Table 1.1.9B in Appendix H.

For simplicity, only total HC emissions will be addressed in this example. Using the two assumptions stated in Section E.2, Step 4, the overlap categories 1, 4, 5, 6, 7, and 9, which all contain catalyst removal, are assumed to have the same emissions impact as from catalyst removal alone. Similarly, the overlap categories 2, 3, 10, and 11, which all contain misfueling, are assumed to have the same emissions impact as from misfueling alone. Category 8, which contains only air pump disablement, experiences the air pump disablement emissions impact.

The excess exhaust emissions due to tampering and misfueling are determined by multiplying the size of each emission impact group, and the appropriate excess emission estimate. The three technology types are then weighted by their fleet fractions from Table 1.1.10C and summed for the combined excess emissions from air pump, catalyst, and misfueling. This calculation is presented in Table E-3.

Table E-3

Example Calculation of Exhaust Emission Impact

| <u>Emission Impact Groups</u> | <u>Overlap Categories</u> | (A) Emission Impact Group Size | (B) Excess Total HC Emissions (g/mi) | (C) Composite Technology Fleet Fraction | Emission Impact (A*B*C) |
|-------------------------------|---------------------------|-----------------------------------|---|--|-------------------------|
| <u>Catalyst with Air Pump</u> | | | | | |
| Air Pump Disablement | 8 | 0.06861 | 0.85 | 0.70 | 0.041 |
| Catalyst Removal | 1,4,5,6,7,9 | 0.03519 | 2.04 | 0.70 | 0.050 |
| Misfueled | 2,3,10,11 | 0.02396 | 1.44 | 0.70 | 0.024 |
| <u>Air Pump Only</u> | | | | | |
| Air Pump Disablement | 1-5,8 | 0.09460 | 0.85 | 0.00 | 0.0 |
| <u>Catalyst Only</u> | | | | | |
| Catalyst Removal | 1,4,5,6,7,9 | 0.04680 | 2.04 | 0.30 | 0.029 |
| Misfueled | 2,3,10,11 | 0.02396 | 1.44 | 0.30 | 0.010 |
| Total Emission Impact (g/mi): | | | | | 0.154 |

The excess idle emissions due to tampering and misfueling are determined similarly, with the exception that excess idle emissions in g/hr are used in the calculation.

PCV and evaporative canister tampering effects are assumed not to overlap with any of the other tampering and misfueling effects discussed above. The excess crankcase emissions due to PCV tampering can be determined by simply multiplying together the evaluation date tampering rate of 0.0150 (from Table E-1), the excess emissions of 1.21 g/mi (from Table 1.1.9C), and technology type fleet fractions of 100.0 percent (from Table 1.1.10C). The calculated evaporative crankcase emissions impact due to PCV tampering is 0.018 g/mi for model year 1982 LDGVs on January 1, 1988.

The calculation of other evaporative HC emissions including tampering are more complicated. First, the two types of evaporative control system tampering to be considered are canister disconnect and fuel cap removal. The rate of canister disconnect is 0.0559 (from Table E-1). The rate of fuel cap removal is 0.0118, which is the rate differences between "both

"canister and cap" and "canister disconnect" categories (i.e., $0.0677 - 0.0559 = 0.0118$, from Table E-1). The fraction of the fleet exhibiting no evaporative control system tampering is 0.9323.

As mentioned in Section E.2 (Step 6), the evaporative emissions impact is estimated from the uncontrolled emission rates. As can be seen from Tables 1.1.9C and 1.1.9D in Appendix H, the uncontrolled hot soak, diurnal, and running loss emissions (like their nontampered counterparts) are dependent on fuel volatility level, ambient temperature, and fuel-metering technology. For simplicity, a certification RVP level of 9.0 psi is assumed. The diurnal emissions are derived from the FTP heat build of 60° to 84°F, the hot soak emissions are estimated at 82°F, and the running loss emissions are at an ambient temperature of 80°F. Further, to estimate hot soak and diurnal emissions, fleet fractions of fuel-metering systems (ported fuel-injected, throttle-body fuel-injected, and carbureted) are also needed. For model year 1982 LDGVs, the fleet fractions of these three technology groups are 0.063, 0.108, and 0.829, respectively (from Table 1.1.10D of Appendix H). The calculation of the uncontrolled evaporative emission rates (g/test for hot soak and diurnal, g/mi for running loss) is presented below.

| <u>Emission Type</u> | <u>Fuel Metering System</u> | <u>Uncontrolled Emissions</u> | <u>Fuel-Metering Technology Fractions</u> | <u>Combined Uncontrolled Emissions</u> |
|----------------------------|-----------------------------|-------------------------------|---|--|
| <u>Canister Disconnect</u> | | | | |
| Hot Soak | Carbureted | 10.36 | 0.829 | |
| Diurnal | Fuel-injected | 5.20 | 0.171 | 9.478 |
| | Carbureted | 14.70 | 0.829 | |
| Running Loss | Fuel-injected | 14.70 | 0.171 | 14.700 |
| | All | 0.52 | 1.0 | 0.520 |
| <u>Fuel Cap Removal</u> | | | | |
| Hot Soak | Carbureted | 0.0 | 0.829 | |
| Diurnal | Fuel-injected | 5.20 | 0.171 | 0.889 |
| | Carbureted | 14.70 | 0.829 | |
| Running Loss | Fuel-injected | 14.70 | 0.171 | 14.700 |
| | All | 1.23 | 1.0 | 1.230 |

The nontampered hot soak and diurnal emissions (g/test) are given in Table 1.1.2A of Appendix H. The nontampered g/mi running loss emissions are from Table 1.1.2C of Appendix H. Table E-4 shows the calculation of evaporative emissions including tampering.

Table E-4

Example Calculation of Evaporative HC
Emissions Including Tampering

| Emission Type | Non-tampered Emissions | Canister Disconnect | | Fuel Cap Removal | | Composite Emissions |
|---------------|------------------------|---------------------|------------------------|------------------|------------------------|---------------------|
| | | Fleet Fraction | Combined Emission Rate | Fleet Fraction | Combined Emission Rate | |
| Hot Soak | 1.80 | 0.9323 | 9.478 | 0.0559 | 0.889 | 0.0118 2.218 |
| Diurnal | 2.29 | 0.9323 | 14.700 | 0.0559 | 14.700 | 0.0118 3.130 |
| Running Loss | 0.24 | 0.9323 | 0.520 | 0.0559 | 1.230 | 0.0118 0.268 |

Appendix F

CALCULATION PROCEDURE FOR VMT VS. AGE DISTRIBUTIONS
FOR HEAVY-DUTY DIESEL-POWERED VEHICLES

In MOBILE4, the VMT distribution for heavy-duty diesel-powered vehicles (HDDVs) in any given calendar year is calculated from the VMT vs. age distributions of four distinct HDDV weight classes. The four weight classes of diesel-powered trucks are:

| <u>Class</u> | <u>Gross Vehicle Weight (Lbs)</u> |
|---------------|-----------------------------------|
| 2B | 8,500 - 10,000 |
| Light (3-5) | 10,001 - 19,500 |
| Medium (6-8A) | 19,501 - 50,000 |
| Heavy (8B) | > 50,000 |

The annual mileage accumulation distributions by age for each weight class, given in Table F-1, are weighted together by their registration fractions in each weight class to derive an overall heavy-duty diesel mileage distribution (under "weighted average" in Table F-1) for each calendar year. The registration fractions are shown at the bottom of Table F-1 for calendar year 1988. These fractions are calculated from the estimated number of vehicles in each weight class for each calendar year (for example, 1988), as shown in Table F-2.

Table F-1

Calendar Year 1988 HDDV VMT Example

| <u>Age</u> | <u>Annual Mileage Accumulation Rates</u> | | | <u>Weighted Average</u> |
|------------|--|--------------------|----------------------|-------------------------|
| | <u>Class 2B</u> | <u>Light (3-5)</u> | <u>Medium (6-8A)</u> | |
| 1 | 17,608 | 23,611 | 43,946 | 86,375 |
| 2 | 16,217 | 20,947 | 40,504 | 79,434 |
| 3 | 14,937 | 18,583 | 37,332 | 73,051 |
| 4 | 13,758 | 16,486 | 34,408 | 67,181 |
| 5 | 12,671 | 14,625 | 31,713 | 61,782 |
| 6 | 11,671 | 12,975 | 29,229 | 56,817 |

Registration fractions for each weight class of HDDVs in 1988* are:

0.2113 0.0321 0.3026 0.4540

* The registration fractions for the four HDDV weight classes are calculated from the total registrations by class (Table F-2) divided by the overall HDDV registrations (last column of Table F-2).

Appendix G

SAMPLE CALCULATION OF MOTOR VEHICLE EMISSIONS

This appendix presents the procedure for calculating emission factors in a step-by-step manner. Although most users of motor vehicle emission factors should rely on computerized calculations (such as MOBILE4), this sample calculation may prove useful to those becoming familiar with the methodologies presented in this document.

For this sample calculation, the light-duty gasoline-powered vehicle (LDGV) hydrocarbon (HC) emissions for January 1, 1988 are computed. It is designed to give the user an understanding of the logical sequence of calculations. An inventory of motor vehicle sources of hydrocarbon emissions should include emissions from the eight vehicle types. For each vehicle type, the exhaust emission factors should be calculated with the equations presented in the corresponding chapter. The resultant exhaust emission factors, are first multiplied by the fraction of vehicles-miles-traveled (VMT) for the respective vehicle types, then are summed up to obtain average grams per mile exhaust emission levels from the entire highway mobile source fleet. For hydrocarbon emission estimates, the crankcase and four other evaporative HC emissions (hot soak and diurnal evaporative, running loss, and refueling emissions) are also calculated. They are then added to the exhaust HC emission estimates.

G.1 DATA REQUIREMENTS

Before determining what data are required, the user should review the conditions under which vehicles are tested in order to ascertain whether these conditions differ from the locality-specific ambient temperature, average speeds, and vehicle operating modes (see Section A.1 in each chapter).

The user should determine the following locality specific data:

1. Daily minimum and maximum ambient temperatures in degrees Fahrenheit.
2. Fractions of January 1 travel, by model year, for each vehicle type (obtained from model year registration distributions and fleet annual mileage accumulation rates).
3. The VMT mix (fractions of total VMT accumulated by each vehicle type).

111

-G-

4. Percent of VMT in cold start and hot start operating modes for light-duty vehicles, light-duty trucks, and motorcycles.
5. The calendar year of evaluation (January 1 of that year).
6. The level of in-use fuel volatility.
7. Any other data required to utilize additional (optional) correction factors.

G.2 DATA USED TO CALCULATE HC EMISSIONS

For this sample calculation, the following conditions are assumed:

1. Daily minimum and maximum ambient temperatures are 60° and 84°F, respectively.
2. National statistics on average fleet annual mileage accumulation rates and vehicle registration by model year are used.
3. The total hydrocarbon emissions (as opposed to nonmethane HC) are calculated for the average speed of 30 mph.
4. The percentages of VMT in the cold start, stabilized, and hot start operating modes are assumed to be 40%, 30%, and 30% respectively, for light-duty vehicles (both catalyst and non-catalyst).
5. The calendar year of evaluation is 1988.
6. No I/M or anti-tampering programs.
7. A certification fuel volatility level of 9.0 psi is assumed.
8. All other conditions are assumed to match the vehicle testing conditions.

G.3 CALCULATION OF EXHAUST EMISSION FACTORS

The equations to calculate the exhaust hydrocarbon emission factor for LDGVs are discussed in Chapter 1.

Since the air conditioning usage (ACCFipt), extra load (XLCFip), trailer towing (TWCFip), and humidity level for NOx (HCF) are assumed to match the basic test conditions, they are all set equal to 1.0 (i.e., they have no effect on the calculations).

G.3.1 Basic Exhaust Emission Levels (BER)

The basic exhaust emission levels for LDGVs are the emission levels in grams per mile, assuming the basic test conditions. The HC exhaust emission levels on January 1, 1988 are listed in Table G-1. Model year specific emission factors for selected calendar years between 1985 and 2020 are presented in Appendix H, Tables R.VT.11A, 11B, and 11C, where R = region (1 = low altitude, 2 = high altitude) and VT = vehicle type.

G.3.2 Operating-Mode/Temperature Correction Factor (OMTCF)

The operating-mode/temperature correction factor can be calculated manually using the generalized equations in Chapter 1. The OMTCF values listed in Table G-1 are calculated in MOBILE4 for a cold start/stabilized/hot start mix of 40%/30%/30%, and an ambient temperature of 78°F (representing a trip- and emission-weighted average temperature for a day with 60°F minimum and 84°F maximum temperatures).

G.3.3 Tampering Offset (OMTTAM)

The effects of tampering (rate of each type of tampering and the associated emission impact) on each model year's emission rate are estimated and corrected for temperature and operating mode, listed also in Table G-1.

G.3.4 Speed Correction Factor (SALCHF)

The average speed used in this example is 30 mph. The speed correction factors, used to correct emissions from 19.6 mph to 30 mph, are shown in the column marked "SALCHF" in Table G-1. If any of the additional correction factors (AC use, trailer towing, extra load) were used in this example, this is the point at which they would be applied.

G.3.5 Travel Weighting Fractions (TF)

In order to calculate the fraction of annual travel by model year, the fraction of in-use vehicles by model year are weighted on the basis of annual rate of mileage accumulation. In many cases, locality specific data on automobile use and registration are readily available. Whenever possible, local data should be used. However, for purposes of this sample calculation, the national average fraction of annual travel are used. (These national average values are presented in Appendix H, Tables R.VT.5, where R = region and VT = vehicle type.) These TF values, also listed in Table G-1, are used to weight the individual model year emission factors together to form a fleet number.

G.3.6 Calculated Exhaust Emission Factors

The final step in the calculation of the exhaust HC emission factor for LDGVs is to multiply the basic emission level (BER) by the operating mode/temperature correction factor (OMTCF), add the tampering offset (OMTTAM), and then multiply this sum by the speed correction factor (SALCHF) and travel fraction (TF). This procedure is shown in Table G-1. The emission factor is expressed in units of grams per vehicle mile traveled.

If the pollutant were CO or NO_x, no further calculations would be needed to estimate the total exhaust emission factor. However, for HC emission estimates, additional calculations discussed in Sections G.3.7 to G.3.9 also need to be performed.

G.3.7 Crankcase and Evaporative HC Emission Levels (CCEVERT)

To calculate the crankcase and evaporative HC emission level, the model year crankcase emissions (CC), plus the tampering offsets, and hot soak (HS), diurnal (DI), including tampering are required. The estimated evaporative and crankcase emissions are shown in Table G-2. Further, the fractions of annual travel by model year (TF) are also required (the same as in Section G.3.5).

G.3.8 Refueling and Running Loss HC Emission Levels

The estimated refueling and running loss emissions are shown in Table G-2. The fractions of annual travel by model year (TF) are also required (the same as in Section G.3.5.).

G.3.9 Total HC Emission Factors

Summing the emission factors from Sections G.3.6 to G.3.8 gives the total HC emission factor. For this example the total HC emission factor is 3.14 grams/mile ($1.788 + 0.654 + 0.300 + 0.397$).

Appendix H

HIGHWAY MOBILE SOURCE EMISSION FACTOR TABLES

All of the emission factor tables for each region and vehicle type are given within this appendix. Each emission factor table has a three digit identification table number. The table numbers have the following format:

R.VT.#

where:

R indicates the region code,
1 = Low altitude non-California region, and,
2 = High altitude non-California region.

VT indicates the vehicle type
1 = LDGV, 2 = LDGT1, 3 = LDGT2, 4 = HDGV,
5 = LDDV, 6 = LDDT, 7 = HDDV, and,
8 = MC.

indicates which of the 16 types of table are referenced.

In addition to this coding scheme for the table numbers, the table titles include the information to avoid confusion. Table H-1 gives a summary of every table and table number for each region. There is a total of 150 tables for each of the two regions presented in this appendix.

Table H-1

**SUMMARY OF THE EMISSION FACTOR TABLE NUMBERS
FOR EACH REGION BY VEHICLE TYPE AND TABLE TYPE**

Note: All table numbers are of the form R.IV.#, where R = Region (1 = low altitude, 2 = high-altitude), IV = Vehicle type code, and # = the table number within each region and vehicle type set of tables.

* Based on calculated hot soak temperature of 82.0F,
 Diurnal temperature rise from 60.0 to 84.0F,
 Fuel RVPs of 9.0 and 11.5 psi with no weathering, tank level of 40.0%.

** Based on averages of 4.21 trips per day and 25.35 miles per day.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

DAF: 0.944

TFNORM: 9253.6

WHERE :

- A = January 1 registration mix from Table 1.1.4A,
- B = Gasoline fleet sales fractions,
- D = Sales weighted fleet mileage accumulation rate from Table 1.1.4A.

NOTE : In general, the travel weighting fractions will change for every calendar year since the sales fraction (column B) changes for almost every model year.

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 1.1.4A.

 ZML = Zero mile level in grams/mile.
 DR = Deterioration rate in grams/mile/10K miles.
 M = Cumulative mileage / 10,000 miles.

* Based on calculated hot soak temperature of 82.0F,
Diurnal temperature rise from 60.0 to 84.0F,
Fuel RVPs of 9.0 and 11.5 psi with no weathering, tank level of 40.0%.

** Based on averages of 4.24 trips per day and 29.05 miles per day.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

NOTE : The fractions given in this table are used in the calculation of the operating-mode/temperature correction factor (OMTCF).

WHERE :

- OMTCF = [(TERM1 + TERM2 + TERM3)/DENOM],
- TERM1 = W * TCF(1)*(B1+D1=M),
- TERM2 = (1-W-X)*TCF(2)*(B2+D2=M),
- TERM3 = X * TCF(3)*(B3+D3=M),
- DENOM = BO + DO=M,
- W = Fraction of VMT in the cold start mode.
- X = Fraction of VMT in the hot start mode.
- TCF(b) = Temperature correction factor for pollutant, model year, for test segment b.
- M = Cumulative mileage / 10,000 miles.

*MY - Indicates the model year.

**E - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, 1EMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 1.2.4A.

*MY

Indicates the model year.

**E

Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table I-2.4A.

* Based on calculated hot soak temperature of 82.0F,
 Diurnal temperature rise from 60.0 to 84.0F,
 Fuel RVPs of 9.0 and 11.5 psi with no weathering, tank level of 40.0%.

** Based on averages of 4.24 trips per day and 30.80 miles per day.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
 + Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
 for ASTM class A/B/C cities. Onboard assumed to start in 1993,
 and apply to LDGVs, LDGTs, and HDGVs.

NOTE : The fractions given in this table are used in the calculation of the operating-mode/temperature correction factor (DMTCF).

WHERE : DMTCF = [(TERM1 + TERM2 + TERM3)/DENOM].
 TERM1 = W * TCF(1)*(B1+D1=M).
 TERM2 = (1-W-X)*TCF(2)*(B2+D2=M).
 TERM3 = X * TCF(3)*(B3+D3=M).
 DENOM = B0 + DO=M,
 W = Fraction of VMT in the cold start mode.
 X = Fraction of VMT in the hot start mode.
 TCF(b) = Temperature correction factor for pollutant, model year, for test segment b.
 M = Cumulative mileage / 10,000 miles.

* Hot Soak emissions = 82F ambient temperature,
 Diurnal emissions = 60 to 84F one hour heat build,
 No fuel weathering, tested at 40% tank level.

*MY - Indicates the model year.
 ** - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20 % of VMT traveled in cold start, 52 % of VMT in stabilized, and 27.3% of VMT in hot start, 60 TO 84F diurnal, /5F for hot soak and running loss emissions, 9.0 psi fuel RVP, 54.57% average in-use fuel tank level, including refueling emissions. Emissions are based on the January 1 mileage accumulation figures given in Table 1.3.4A.

*MY Indicates the model year.
 **E Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table I.3.4A.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

*MY -- Indicates the model year.
 **E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F., 60/10/84F diurnal, 75F for hot soak and running loss emissions, 9.0 psi fuel RVP, 54.57% average in-use fuel tank level, including refueling emissions. Emissions are based on the January 1 mileage accumulation figures given in Table 1.4.4.

N
N
O

*MY

Indicates the model year.

**E

Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 1.4.4.

TABLE 1.4.11C

DATE : MAY 19, 1989

BY MODEL YEAR EMISSION LEVELS FOR LOW ALTITUDE
HEAVY DUTY GASOLINE POWERED VEHICLES
NOx

N
N

* MY Indicates the model year.
 ** E Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 1.4.4.

*MY Indicates the model year.

**E Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table 1.5.4A.

NOTE : The fractions given in this table are used in the calculation of the operating-mode/temperature correction factor (OMTCF).

WHERE : OMTCF = [(TERM1 + TERM2 + TERM3)/DENOM].
 TERM1 = W = TCF(1)*(B1+D1*M).
 TERM2 = (1-W-X)=TCF(2)=(B2+D2*M).
 TERM3 = X = TCF(3)=(B3+D3*M).
 DENOM = B0 + D0*M.
 W = Fraction of VMT in the cold start mode.
 X = Fraction of VMT in the hot start mode.
 TCF(b) = Temperature correction factor for pollutant, model
 year, for test segment b.
 M = Cumulative mileage / 10,000 miles.

*MY Indicates the model year.
**E Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table I.6.4A.

*MY - Indicates the model year.

**E - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F., 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table I.6.4A.

242

* Default information that may be altered by the MOBILE4 user with information about the local area. This mileage distribution is applicable to calendar year 1988 only.

** The indices refer to the most recent model year vehicles in any given calendar year. Index 1 references the newest model year vehicles and index 20+ references the oldest model year vehicles.

*** Sales weighted fleet mileage accumulation adjusted to January 1, where: JMAR(1) = 0 and,
JMAR(MY1) = MAR(MY1-1), MY1 = 2,...,20+.

N MY - Indicates the model year.
 V E - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 1.7.4.

*MY -- Indicates the model year.

** -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 1.7.4.

N
U
W

*MY - Indicates the model year.

**E - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 1.7.4.

*MY - Indicates the model year.

** - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in table 1.B.4.

* Based on calculated hot soak temperature of 82.0F,
Diurnal temperature rise from 60.0 to 84.0F,
Fuel RVPs of 9.0 and 11.5 psi with no weathering, tank level of 40.0%.

** Based on averages of 4.21 trips per day and 25.35 miles per day.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

WHERE :

- A = January 1 registration mix from Table 2.1.4A,
- B = Gasoline fleet sales fractions,
- D = Sales weighted fleet mileage accumulation rate from Table 2.1.4A.

NOTE : In general, the travel weighting fractions will change for every calendar year since the sales fraction (column B) changes for almost every model year.

* WHERE :

- TCF(b) = High temperature correction factor for appropriate pollutant, ambient temperature, and model year, for test segment b.
- T = Ambient temperature (Fahrenheit).
- TC(b) = High temperature correction factor coefficient for appropriate pollutant, temperature, and model year, for test segment b.
- TRCF(b) = High temperature and fuel RVP correction factor for appropriate pollutant, ambient temperature, fuel RVP, and model year, for test segment b.
- RC(b) = Fuel RVP correction factor coefficient for appropriate pollutant, fuel RVP, and model year, for test segment b.
- RVP = Fuel volatility in psi.
- TRC(b) = Combined temperature and fuel RVP correction factor coefficient for appropriate pollutant, fuel RVP, ambient temperature, and model year, for test segment b.

NOTE : The temperature correction factor is used in conjunction with the correction factor given in Table 2.1.7C.

NOTE : The fractions given in this table are used in the calculation of the operating-mode/temperature correction factor (OMTCF).

WHERE : $OMTCF = [(TERM1 + TERM2 + TERM3)/DENOM]$.

TERM1 = $W = TCF(1) = (B1+D11=M)$, or $=[B1+D11=5.0+D12=(M-5.0)]$.

TERM2 = $(1-W-X)=TCF(2)=(B2+D21=M)$, or $=[B2+D21=5.0+D22=(M-5.0)]$.

TERM3 = $X = TCF(3)=(B3+D31=M)$, or $=[B3+D31=5.0+D32=(M-5.0)]$.

DENOM = $B0+D01=M$, or $= B0+D01=5.0+D02=(M-5.0)$.

W = Fraction of VMT in the cold start mode.

X = Fraction of VMT in the hot start mode.

TCF(b) = Temperature correction factor for pollutant/model year/test segment b.

M = Cumulative mileage / 10,000 miles.

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start, 60 TO 84F diurnal, 75F for hot soak and running loss emissions, 9.0 psi fuel RVP, 54.57% average in-use fuel tank level, including refueling emissions. Emissions are based on the January 1 mileage accumulation figures given in Table 2.1.4A.

BY MODEL YEAR EMISSION LEVELS FOR HIGH ALTITUDE
LIGHT DUTY GASOLINE POWERED VEHICLES

*MY Indicates the model year.

**E Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 2.1.4A.

*MY - Indicates the model year.
 **E - Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20% of VMT traveled in cold start, 52% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 2.1.4A.

* Based on calculated hot soak temperature of 82.0F,
Diurnal temperature rise from 60.0 to 84.0F,
Fuel RVPs of 9.0 and 11.5 psi with no weathering, tank level of 40.0%.

** Based on averages of 4.24 trips per day and 29.05 miles per day.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

WHERE :

- A = January 1 registration mix from Table 2.2.4A,
- B = Gasoline fleet sales fractions,
- D = Sales weighted fleet mileage accumulation rate from Table 2.2.4A.

NOTE : In general, the travel weighting fractions will change for every calendar year since the sales fraction (column B) changes for almost every model year.

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start, 60 TO 84F diurnal, 75F for hot soak and running loss emissions, 9.0 psi fuel RVP, 54.57% average in-use fuel tank level, including refueling emissions. Emissions are based on the January 1 mileage accumulation figures given in Table 2.2.4A.

W *MY -- Indicates the model year.

N **E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20% of VMT traveled in cold start, 52% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 2.2.4A.

* Based on calculated hot soak temperature of 82.0F,
Diurnal temperature rise from 60.0 to 84.0F,
Fuel RVPs of 9.0 and 11.5 psi with no weathering, tank level of 40.0%.

** Based on averages of 4.24 trips per day and 30.80 miles per day.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

NOTE : The fractions given in this table are used in the calculation of the operating-mode/temperature correction factor (DMTCF).

WHERE : DMTCF = [(TERM1 + TERM2 + TERM3)/DENOM].

TERM1 = W = TCF(1)*(B1+D1=M).

TERM2 = (1-W-X)=TCF(2)*(B2+D2=M).

TERM3 = X = TCF(3)*(B3+D3=M).

DENOM = B0 + DO=M.

W = Fraction of VMT in the cold start mode.

X = Fraction of VMT in the hot start mode.

TCF(b) = Temperature correction factor for pollutant, model year, for test segment b.

M = Cumulative mileage / 10,000 miles.

W F U

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start, 60 to 84F diurnal, 75F for hot soak and running loss emissions, 9.0 psi fuel RVP, 54.57% average in-use fuel tank level, including refueling emissions. Emissions are based on the January 1 mileage accumulation figures given in Table 2.3.4A.

LW

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20% VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 2.3.4A.

* Refueling Emissions (g/mi) = [Displacement (g/gal)
+ Spillage (g/gal)] / Fuel Economy (mi/gal).

** Volatility control assumed to start in 1992, with 7.0/7.8/9.0 RVP fuels
for ASTM class A/B/C cities. Onboard assumed to start in 1993,
and apply to LDGVs, LDGTs, and HDGVs.

* My. Indicates the model year.

** E. Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 2.4.4.

TABLE 2.4.11C

DATE : MAY 19, 1989

BY MODEL YEAR EMISSION LEVELS FOR HIGH ALTITUDE
HEAVY DUTY GASOLINE POWERED VEHICLES
NOx

NOTE : The fractions given in this table are used in the calculation of the operating-mode/temperature correction factor (OMTCF).

WHERE : OMTCF = [(TERM1 + TERM2 + TERM3)/DENOM].
 TERM1 = W = TCF(1)=(B1+D1=M).
 TERM2 = (1-W-X)=TCF(2)=(B2+D2=M).
 TERM3 = X = TCF(3)=(B3+D3=M).
 DENOM = B0 + D0=M.
 W = Fraction of VMT in the cold start mode.
 X = Fraction of VMT in the hot start mode.
 TCF(b) = Temperature correction factor for pollutant, model
 year, for test segment b.
 M = Cumulative mileage / 10,000 miles.

*MY

Indicates the model year.

**E

Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table 2.5.4A.

103

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F., 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table 2.5.4A.

BY MODEL YEAR EMISSION LEVELS FOR HIGH ALTITUDE
LIGHT DUTY DIESEL POWERED VEHICLES
NOx

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F., 20% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table 2.5.4A.

W • MY -- Indicates the model year.
 88 • E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on January 1 mileage accumulation figures given in Table 2.6.4A.

W
 *MY -- Indicates the model year.
 **E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP-75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 2.7.4.

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 2.7.4.

*MY -- Indicates the model year.
 **E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F. Emissions are based on the January 1 mileage accumulation figures given in Table 2.7.4.

*MY -- Indicates the model year.

**E -- Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 19.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start, 60 TO 84F diurnal, 75F for hot soak 9.0 psi fuel RVP, 54.57% average in-use fuel tank level. Emissions are based on January 1 mileage accumulation figures given in Table 2.8.4.

TABLE 2.A.11C

DATE : MAY 19, 1989

**BY MODEL YEAR EMISSION LEVELS FOR HIGH ALTITUDE
MOTORCYCLES
NOx**

*MY -- Indicates the model year.

****E --** Indicates the average grams/mile emission level for model year "MY" on January 1 of the given calendar year. These emission levels are calculated for the basic test conditions: 18.6 MPH, TEMP=75 Degrees F, 20.6% of VMT traveled in cold start, 52.1% of VMT in stabilized, and 27.3% of VMT in hot start. Emissions are based on the January 1 mileage accumulation figures given in Table 2.B.4.

Appendix I

EMISSION SENSITIVITY TABLES - ALL VEHICLES COMBINED

This appendix contains, for all mobile sources combined, for several calendar years between 1980 and 2010:

1. average exhaust emission factors for various ambient temperatures, cold/hot start VMT weightings, and for a range of average speed combinations, and,
2. average emission factors by component under FTP cold/hot start VMT weightings and FTP average speed for different levels of fuel volatility (in psi), and for a range of "typical" ambient temperature profiles.

This appendix includes one case that represents the average national emission factors as generated from the standard test conditions (in Tables 1.4, 1.10, and 1.16 for exhaust NMHC, CO, and NO_x, respectively, and in Table 2.1 for emissions by component) as well as other scenarios that can be used to assess the sensitivity of the emission factors to changing input conditions. All emission factors are given in units of grams of pollutant per vehicle mile traveled, with the exception of idle emission factors which are given in units of grams of pollutant per hour time. The exhaust hydrocarbon emissions are nonmethane. The evaporative HC emissions include the crankcase emissions.

Emission factors presented in this section are intended to assist those individuals interested in compiling approximate mobile source emission estimates for large areas, such as an individual air quality control region or the entire nation.

The emission factor calculation techniques presented in this document are strongly recommended for the formulation of localized emission estimates required for air quality modeling or for the evaluation of air pollutant control strategies. Many factors, which vary with geographic location and estimation situation, can affect emission estimates considerably. The factors of concern include: average speed, percentage of VMT in cold/hot start vehicle operation, percentage of travel by vehicle type, average ambient temperature profile, level of fuel volatility, air conditioning usage, vehicle load, trailer towing, and humidity. Clearly, the innumerable combinations make it impossible to present mobile source emission factors for each application. An effort has been made, therefore, to present emission factors for a range of conditions. The following conditions are considered for each of these cases:

1. The VMT mixes are those calculated from MOBILE4. They are as follows:

| <u>Calendar Year</u> | <u>LDGV</u> | <u>LDGT1</u> | <u>LDGT2</u> | <u>HDGV</u> | <u>LDDV</u> | <u>LDDT</u> | <u>HDDV</u> | <u>MC</u> |
|----------------------|-------------|--------------|--------------|-------------|-------------|-------------|-------------|-----------|
| 1980 | 0.708 | 0.129 | 0.085 | 0.015 | 0.006 | 0.001 | 0.045 | 0.010 |
| 1988 | 0.708 | 0.128 | 0.086 | 0.015 | 0.013 | 0.004 | 0.036 | 0.010 |
| 1990 | 0.710 | 0.127 | 0.086 | 0.015 | 0.013 | 0.004 | 0.034 | 0.010 |
| 1995 | 0.703 | 0.122 | 0.085 | 0.015 | 0.023 | 0.011 | 0.030 | 0.010 |
| 2000 | 0.693 | 0.116 | 0.085 | 0.015 | 0.035 | 0.017 | 0.029 | 0.010 |
| 2010 | 0.685 | 0.112 | 0.086 | 0.015 | 0.043 | 0.021 | 0.029 | 0.010 |

2. For the exhaust emission factor tables (designated by 1.x), each table represents one average speed. There are 6 different speeds: 2.5, 5.0, 10.0, 19.6, 35.0, and 55.0 mph. Each table presents six calendar years: 1980, 1988, 1990, 1995, 2000, and 2010. Each calendar year presents 35 combinations of five temperatures and seven operating modes. The five temperatures are: 0°, 25°, 50°, 75°, and 100°F. The seven operating mode combinations are shown in the following:

Operating Mode Combinations

| <u>MOBILE4 Input</u> | <u>Description</u> |
|----------------------|--|
| 0/0/0 | 100% Stabilized |
| 0/100/0 | 100% Hot Start |
| 100/0/100 | 100% Cold Start |
| 50/0/50 | 50% Cold Start, 50% Stabilized |
| 0/50/0 | 50% Hot Start, 50% Stabilized |
| 50/50/50 | 50% Cold Start, 50% Hot Start |
| 20.6/27.3/20.6 | 20.6% Cold Start, 52.1% Stabilized, and 27.3% Hot Start (FTP conditions) |

3. For the emission factors by component tables (designated by 2.x), all emissions are based on FTP operating mode with 19.6 mph average speed. Each table represents one typical ambient temperature profile. The given temperature profile in MOBILE4 determines the ambient temperatures used to calculate all emissions: exhaust HC, CO, and NOx, and evaporative hot soak, diurnal, and running loss emissions. The four typical temperature profiles used are:

416

| <u>Description of Temperature Profile</u> | Temperature in °F | | <u>Exhaust</u> | <u>Hot Soak</u> | <u>Running Loss Emissions</u> |
|---|------------------------|----------------|----------------|-----------------|-------------------------------|
| | <u>Diurnal Minimum</u> | <u>Maximum</u> | | | |
| FTP Conditions | 60.0 | 84.0 | 78.1 | 80.2 | 81.0 |
| ASTM Class A | 66.9 | 95.1 | 88.3 | 90.3 | 91.3 |
| ASTM Class B | 71.2 | 91.6 | 87.0 | 88.1 | 88.8 |
| ASTM Class C | 65.9 | 85.0 | 80.6 | 81.8 | 82.5 |

4. Each table presents "six" calendar years. Each calendar year presents six level of fuel volatilities: 7.0, 8.0, 9.0, 10.0, 10.4, and 11.7 psi RVP. The seven components are:

- Evaporative HC Emissions (hot soak and diurnal),
- Refueling Loss Emissions,
- Running loss Emissions,
- Exhaust NMHC Emissions,
- Combined NMHC (sum of the above four) Emissions,
- Exhaust CO Emissions, and
- Exhaust NO_x Emissions.

Appendix J

EMISSION SENSITIVITY TABLES BY VEHICLE TYPE

Appendix J is arranged in the same way as the Appendix I, except that the emission factors are disaggregated by vehicle type. The LDGT category combines LDGT1s and LDGT2s. For the emission factors by component tables, only LDGVs, LDGTs, and HDGVs are given. An additional table (Table 3.1) provides hot stabilized idle emission factors (NMHC, CO, and NOx) for both low- and high-altitude regions and six calendar years.

TABLE 3.1 : FOR HOT STABILIZED IDLE EMISSIONS.

LOS

Appendix K

EMISSION SENSITIVITY TABLES (A/C, EXTRA LOAD, AND TRAILER TOWING)

The following tables show the sensitivity of the MOBILE4 emission factors to variations in air conditioner usage, extra vehicle loads, and the percentage of vehicles towing trailers. The LDGT category is a weighted average of LDGT1s and LDGT2s. The following conditions are included:

Altitudes: Low, High

Air Conditioner Usage: 0%, 50%, 100%

Extra Load Percentage: 0%, 5%, 10%, 15%

Trailer Towing Percentage: 0%, 5%, 10%

TABLE 18: NOx @ 100 % A/C USAGE

Reproduced by NTIS
National Technical Information Service
U.S. Department of Commerce
Springfield, VA 22161

NTIS does not permit return of items for credit or refund. A replacement will be provided if an error is made in filling your order, if the item was received in damaged condition, or if the item is defective.

This report was printed specifically for your order from our collection of more than 2 million technical reports.

For economy and efficiency, NTIS does not maintain stock of its vast collection of technical reports. Rather, most documents are printed for each order. Your copy is the best possible reproduction available from our master archive. If you have any questions concerning this document or any order you placed with NTIS, please call our Customer Services Department at (703)487-4660.

Always think of NTIS when you want:

- Access to the technical, scientific, and engineering results generated by the ongoing multibillion dollar R&D program of the U.S. Government.
- R&D results from Japan, West Germany, Great Britain, and some 20 other countries, most of it reported in English.

NTIS also operates two centers that can provide you with valuable information:

- The Federal Computer Products Center - offers software and datafiles produced by Federal agencies.
- The Center for the Utilization of Federal Technology - gives you access to the best of Federal technologies and laboratory resources.

For more information about NTIS, send for our FREE *NTIS Products and Services Catalog* which describes how you can access this U.S. and foreign Government technology. Call (703)487-4650 or send this sheet to NTIS, U.S. Department of Commerce, Springfield, VA 22161. Ask for catalog, PR-827.
